CONTENTS

Preface	xvii
----------------	-------------

VOLUME 1

Chapter 1	A Social-Ecological Approach to Understanding Cyberbullying Involvement <i>Michelle F. Wright</i>	1
Chapter 2	Past, Present, and Future Theoretical Developments in Predicting Cyberbullying Behavior <i>Christopher P. Barlett</i>	13
Chapter 3	Measuring Cyberbullying: Towards an Integrative Approach to Assessment <i>Julia Fluck</i>	29
Chapter 4	Adolescents' Perceptions of Suffered and Committed Cyber-Aggressive Behavior <i>Isabel Cuadrado-Gordillo and Inmaculada Fernández-Antelo</i>	49
Chapter 5	Examination of Cyberbullying Experiences among Students from Different Age Groups <i>Sevda Arslan and Ayşegül Selcen Güler</i>	67
Chapter 6	Gender Differences in Cyberbullying Perpetration: The Role of Moral Disengagement and Aggression <i>Özgür Erdur-Baker, İbrahim Tanrıkulu and Çiğdem Topcu</i>	77
Chapter 7	Gender Differences in Peer-Pressured Sexting <i>Elizabeth Englander and Meghan McCoy</i>	97
Chapter 8	The Role of Emotional Processes in (Cyber)bullying <i>Enrica Ciucci and Andrea Baroncelli</i>	105
Chapter 9	Who is Who in Cyberbullying? Conceptual and Empirical Perspectives on Bystanders in Cyberbullying <i>Jan Pfetsch</i>	121

Chapter 10	The Adolescent-Parent Context and Positive Youth Development in the Ecology of Cyberbullying <i>Lawrence B. Schiamberg, Gia Barboza, Grace Chee and Meng Chuan Hsieh</i>	149
Chapter 11	Social-Ecological Perspective: Power of Peer Relations in Determining Cyber-Bystander Behavior <i>Deborah Price and Deborah Green</i>	179
Chapter 12	English Teachers and Cyberbullying: A Qualitative Exploration of the Stakeholders' Perceptions and Experience of the Phenomenon <i>Magdalena Marczak and Iain Coyne</i>	195
Chapter 13	Exposure to Antisocial and Risk Behavior Media Content Stimulates Cyberbullying Behavior: The Cyclic Process Model <i>Anouk den Hamer and Elly Konijn</i>	221
Chapter 14	Cyberbullying: The Need to Extend the Concept beyond Peer Aggression <i>Jacek Pyżalski</i>	239
Chapter 15	Does Culture Matter? Cyberbullying Perpetration and Cybervictimization in the Mediterranean Sea Region <i>Fatih Bayraktar</i>	249
Chapter 16	Risks Factors in Cyberbullying: The Moderating Role of Culture <i>Natalie Wong</i>	265
Chapter 17	Cyberbullying in Europe: A Review of Evidence from Cross-National Data <i>Anke Görzig and Hana Machackova</i>	291
Chapter 18	The Role of Ethnicity and Culture in Cyberbullying Experiences among Youth <i>Guadalupe Espinoza and Jaana Juvonen</i>	323
Chapter 19	Approaches to Reducing Cyberbullying: Change the Bully, Change the Bystander, or Change the Victim? <i>Ashley N. Doane, Matthew R. Pearson and Michelle L. Kelley</i>	335
Chapter 20	Cyberbullying Requires More Than a Virtual Response: Suggestions for Prevention <i>V. Skye Wingate and Jessica A. Minney</i>	353
Chapter 21	In Search of a Simple Method: Is a Human Face an Effective, Automatic Filter Inhibiting Cyberbullying? <i>Anna Szuster, Julia Barlińska and Magdalena Kozubal</i>	375

Chapter 22	An Analysis of Cyberbullying Victimization Case Studies in the Context of the Social-Ecological Theory <i>William Stanley Pendergrass and Michelle F. Wright</i>	397
-------------------	---	------------

Chapter 23	Concluding Remarks on the Social-Ecological Approach to Understanding Cyberbullying <i>Michelle F. Wright</i>	409
-------------------	--	------------

VOLUME 2

Chapter 24	Preschool Teachers' Perceptions about the Definition and Manifestations of Bullying in Early Childhood Settings <i>Eleni N. Nikolaou and Georgios M. Markogiannakis</i>	413
-------------------	--	------------

Chapter 25	Teachers' Attitudes towards Bullying <i>Christina F. Papaeliou</i>	425
-------------------	---	------------

Chapter 26	Bullying via Violent Communication by Early Childhood Education Teachers during Teaching Processes: Two Observational Studies <i>Panagiotis J. Stamatis</i>	435
-------------------	--	------------

Chapter 27	Nonverbal Expressions Related to Violent Communication and Bullying in Kindergarten <i>Afrodite V. Ntouka and Panagiotis J. Stamatis</i>	447
-------------------	---	------------

Chapter 28	Classroom Noise and Miscommunication as Modern Forms of Violent Communication and Bullying <i>Panagiotis J. Stamatis</i>	459
-------------------	---	------------

Chapter 29	Observing Kinesics of Violent Communication and Bullying in Early Childhood Classrooms <i>Panagiotis J. Stamatis and Kyriakos A. Marousis</i>	473
-------------------	--	------------

Chapter 30	Current Theoretical Discussions on Characteristics of Cyberaggression, School Miscommunication and Bullying in Early Education <i>Timothy Phoenix Oblad and McKinsie Kay Oblad</i>	483
-------------------	---	------------

Chapter 31	Preschool Teachers' Perceptions about the Effective Intervention for Bullying at the Preschool Age <i>Eleni N. Nikolaou and Georgios M. Markogiannakis</i>	497
-------------------	---	------------

Chapter 32	Teaching Social Skills, Empathy and Assertiveness by Teachers and Parents to Prevent Early Childhood Violent Communication and Bullying: Towards a Nonviolent Communication Education <i>Panagiotis J. Stamatis and Afrodite V. Ntouka</i>	507
-------------------	---	------------

Chapter 33	Literature and Novels as Teaching Strategies for Violent Communication and Early Childhood Bullying Prevention <i>Panagiotis J. Stamatis and Evangelia G. Raptou</i>	521
-------------------	---	------------

Chapter 34	Social Antecedents of Bullying: When Does Peer Interaction Become Interpersonal Rejection? <i>Anna Polemikou</i>	533
Chapter 35	Prospects of Interactive Digital Storytelling Applications in Prevention and Treatment of Bullying in Preschool Education <i>Anastasia G. Konstantopoulou, Eleni N. Nikolaou, Georgios N. Fesakis and Stamatia P. Volika</i>	545
Chapter 36	How to Prepare Cross-National Bullying Studies: Conceptualization and Operationalization Differences <i>Dalhee Yoon and Daniel J. Flannery</i>	565
Chapter 37	Gender Differences in Bullying and Suicide <i>Jane Timmons-Mitchell and Seungjong Cho</i>	577
Chapter 38	The Influence of Parenting on School Bullying: Does Child Gender Matter? <i>Karyn L. Healy</i>	605
Chapter 39	Prevention and Psycho-Pedagogical Correction of Bullying in School: Russian Perspective <i>Roza A. Valeeva and Laysan A. Ribakova</i>	625
Chapter 40	Framing School Bullying as Reflection of Deteriorating Basotho Moral Principles <i>Paseka Andrew Mosia</i>	655
Chapter 41	Discrimination and Bullying in an Elementary School in Java, Indonesia <i>Margaret E. Shore and Riana Cahyani</i>	665

VOLUME 3

Chapter 42	Moral Disengagement as an Adaptive Strategy in the Face of Violent Behaviour among Peers <i>Isabel Cuadrado-Gordillo, Inmaculada Fernández-Antelo and Guadalupe Martín-Mora Parra</i>	699
Chapter 43	Bullying among Health Care Providers <i>Sergey Pisklakov, Ming Xiong and Anuradha Patel</i>	719
Chapter 44	Cyberbullying <i>Caleb McCoy, Marisa Potate and Cliff McKinney</i>	725
Chapter 45	Bullying, Personal Self-Regulation, Resilience, Coping Strategies and Engagement-Burnout: Implications for an Intervention with University Students <i>Jesús de la Fuente, Lucía Zapata, M. Mariano Vera, Mari Carmen González-Torres and Raquel Artuch Garde</i>	737

Chapter 46	From Bullying to Pandemy of Terrorism: Synergetic Bio-Psycho-Socio-Spiritual Metodology of Mental Health Protection <i>Pavel Ivanovich Sidorov</i>	755
Chapter 47	Bullying Interventions <i>Mary Ward Pollard, Courtney Walker and Janet W. Kwan</i>	793
Chapter 48	Cyberbullying Validation <i>Vinita Nahar, Xue Li and Chaoyi Pang</i>	801
Chapter 49	Cyberbullying Prevalence - Medium, Motive and Reaction <i>Vinita Nahar, Xue Li and Chaoyi Pang</i>	823
Chapter 50	Modulating Variables of Violent Behavior of Aggressive-Victims of Bullying <i>Isabel Cuadrado-Gordillo and Inmaculada Fernández-Antelo</i>	835
Chapter 51	Bullying among Training School Male Adolescents and Male Adult Prisoners: Descriptive Analysis <i>Kristi Kõiv and Liine Maasikas</i>	855
Chapter 52	Coping Strategies and Cognitive Processes Related to Peer Victimization and the Role of Intervention Programs <i>Jennifer M. Knack, Madeline Rex-Lear, Alanna Wormwood and Aaliyah Gibbons</i>	871
Chapter 53	Bullying among Male Athletes: A Contextual Examination <i>Jesse A. Steinfeldt, Nicole T. Gabana and Matthew D. Powless</i>	895
Chapter 54	Cyberbullying: Bullying Gone Digital <i>Michelle F. Wright and William Stanley Pendergrass</i>	911
Chapter 55	School and Peer Contexts of Bullying <i>Michelle F. Wright</i>	933
Chapter 56	Cyberbullying and Students' Engagement in School: A Literature Review <i>Feliciano H. Veiga, Fernanda García, Ana Tomás Almeida, Suzana Nunes Caldeira and Diana Galvão</i>	949
Chapter 57	Bullying and Moral Reasoning. The Influence of Life Values and Culture on Italian Teenagers' Self-Assertion <i>Brighi Antonella, Giancesini Giovanna and Melotti Giannino</i>	961
Chapter 58	Bullying as an Organizational Safety Issue: Do Different Types of Bullying Lead to Different Litigated Outcomes? <i>Helen LaVan, Yvette P. Lopez and Wm. Marty Martin</i>	981
Chapter 59	Bystander Position-taking in School Bullying: The Role of Positive Identity, Self-efficacy and Self-determination <i>Sandra K. M. Tsang, Eadaoin K. P. Hui and Bella C. M. Law</i>	993

Chapter 60	Combating School Bullying through Developmental Guidance for Positive Youth Development and Promoting Harmonious School Culture <i>Eadaoin K. P. Hui, Sandra K. M. Tsang and Bella C. M. Law</i>	1005
Chapter 61	Determining Adolescents' Risk for Involvement in Bullying or Cyberbullying: A Review of Two Studies <i>Elizabeth L. W. McKenney, Amanda M. Cole, Lisa M. Young, Emily J. Krohn, Stephen D. A. Hupp and Jeremy D. Jewell</i>	1019
Chapter 62	School Based Bullying in Ireland – A Cause for Concern? A Review of Research from Northern Ireland and the Republic of Ireland <i>Conor Mc Guckin, Pauline K. Cummins and Christopher Alan Lewis</i>	1039
VOLUME 4		
Chapter 63	Youth Cyber-Bullying: Risks, Intervention and Prevention <i>Tali Heiman and Dorit Olenik Shemesh</i>	1065
Chapter 64	Cyber-Bullying: Emergence, Current Status and Future Trends <i>Ria Hanewald</i>	1083
Chapter 65	Online Social Networking Behaviours, Cyber-Bullying, Mental Health and Behavioural Functioning in Australian Students <i>Julian J. Dooley and Adrian J. Scott</i>	1099
Chapter 66	Does the Cyberbullying Prevention Program Surf-Fair Work? An Evaluation Study <i>Stephanie Pieschl and Sina Urbasik</i>	1111
Chapter 67	What Can High Schools Do to Prevent Cyber Bullying? <i>Ariel A. Williamson, Beatriz Lucas-Molina and Nancy G. Guerra</i>	1131
Chapter 68	Progress and Limitations in the Measurement of Cyberbullying <i>Rebecca Dredge, John Gleeson and Xochitl de la Piedad Garcia</i>	1151
Chapter 69	Changing the Student Experience of Cyberbullying Through a Cyber-Safety Program <i>Ria Hanewald</i>	1169
Chapter 70	Setting an Agenda for Future Research into Cyberbullying Using Social Network Analysis <i>Denis Wegge, Katrien Van Cleemput, Heidi Vandebosch and Steven Eggermont</i>	1183
Chapter 71	Concepts of Bullying: Developmental and Cultural Aspects <i>Peter K Smith and Claire P Monks</i>	1205
Chapter 72	The Development of Bullying <i>Debra Pepler, Wendy Craig, Depeng Jiang and Jennifer Connolly</i>	1217

Chapter 73	School Bullying: Its Nature and Ecology <i>Dorothy L. Espelage and Lisa De La Rue</i>	1225
Chapter 74	Bullying among Siblings <i>Dieter Wolke and Alexandra J Skew</i>	1241
Chapter 75	Bullying: A Stepping Stone to Dating Aggression? <i>Wendy L. Josephson and Debra Pepler</i>	1257
Chapter 76	Workplace Bullying: The Case of Teen Workers <i>Loraleigh Keashly</i>	1279
Chapter 77	Bullying and Gangs <i>Rob White and Ron Mason</i>	1293
Chapter 78	Bullying Victimization among 13 to 15 Year Old School Children: Results from Two Comparative Studies in 66 Countries and Regions <i>Pernille Due and Bjørn Evald Holstein</i>	1303
Chapter 79	Psychiatric Conditions Associated with Bullying <i>Kirsti Kumpulainen</i>	1317
Chapter 80	Bullying and Suicide <i>Young Shin Kim and Bennett Leventhal</i>	1331
Chapter 81	Morbidity among Bystanders of Bullying Behavior at School <i>Ian Rivers</i>	1353
Chapter 82	Public Health, Safety and Educational Risks Associated with Bullying Behaviors in American Adolescents <i>Jorge Srabstein and Thomas Piazza</i>	1365
Chapter 83	Is there a Syndrome of Bullying? <i>Jorge Srabstein and Thomas Piazza</i>	1377
Chapter 84	Deaths Linked to Bullying and Hazing <i>Jorge Srabstein</i>	1387
Chapter 85	Interventions to Reduce Bullying <i>Ken Rigby and Phillip Slee</i>	1393
Chapter 86	Prevention of Public Health Risks Linked to Bullying: A Need for a Whole Community Approach <i>Jorge Srabstein, Paramjit Joshi, Pernille Due, Joseph Wright, Bennett Leventhal, Joav Merrick, Young-Shin Kim, Tomas Silber, Kirsti Kumpulainen, Edgardo Menvielle and Karen Riibner</i>	1419
Chapter 87	Towards a Detection of Bullying Related Morbidity <i>Jorge Srabstein</i>	1435

VOLUME 5

Chapter 88	Coping Strategies of Secondary School Students Experiencing Bullying: Frequency, Type of Bullying and Psychosocial Difficulties <i>I. Bibou-Nakou and A. Markos</i>	1447
Chapter 89	Parental Views of Children's Bullying Experience, Coping Strategies and their Association with Parenting Practices <i>S. Karga, I. Bibou-Nakou and G. Giaglis</i>	1475
Chapter 90	Bullying in Childhood and Adolescence: Modifying Factors, Impact on Psychosocial Well-Being, and Intervention Strategies <i>Shannon Cheek, Griffin Alexander Stout and Elise D. Berlan</i>	1511
Chapter 91	School Bullying and Health Problems: A Developmental Examination of Predictive and Protective Factors and Coping Strategies <i>Jennifer M. Knack, Steven Arnocky, Crystal Lawton, Mariah Wallace and Jessica Sussman</i>	1533
Chapter 92	The Implementation of a Statewide Bullying Prevention Program and Its Impact on Schools and Communities <i>Betsy Schroeder, Allison Messina, Diana Schroeder, Shiryl Barto and Matthew Masiello</i>	1555
Chapter 93	Personal and Environmental Predictors of School Bullying and its Emotional Consequences <i>Dario Bacchini, Gaetana Affuso, Serena Aquilar and Maria Concetta Miranda</i>	1565
Chapter 94	Bullying/Victimization in Preschool Children: Intrapersonal and Contextual Factors <i>Maria Vlachou, Kafenia Botsoglou and Eleni Andreou</i>	1597
Chapter 95	Discordances in Adolescents' Adoption of Perspectives on Bullying, and their Importance for Dealing with the Problem <i>Isabel Cuadrado-Gordillo and Inmaculada Fernández-Antelo</i>	1623
Chapter 96	Why Do Bullies Bully? Reputation as a Predictor of Bullying <i>Stephen Houghton, Annemaree Carroll, Carol Tan and Elijah Nathan</i>	1647
Chapter 97	The Role of Father Involvement in Children's Bullying Behavior: An Overview of the Literature <i>Theodoros Giovazolias and Olga Themeli</i>	1667
Chapter 98	Bullying Victimization among In-School Adolescents <i>Patti Herring, Seter Siziya, Sricharan Pasupulati, Emmanuel Rudatsikira and Adamson S Muula</i>	1683

Chapter 99	Children, Violence and Bullying <i>Joav Merrick, Isack Kandel and Hatim A. Omar</i>	1691
Chapter 100	Botswana: Bullying Victimization among School-Going Adolescents <i>Patti Herring, Seter Siziya, Sricharan Pasupulati, Emmanuel Rudatsikira and Adamson S Muula</i>	1697
Chapter 101	Workplace and Bullying <i>Said Shahtahmasebi</i>	1705
Chapter 102	Student Bullying: Overview of Research, Federal Initiatives, and Legal Issues <i>Gail McCallion and Jody Feder</i>	1713
Chapter 103	White House Conference on Bullying Prevention <i>The White House</i>	1741
Chapter 104	Correlates of Bullying Victimization among In-School Adolescents in the 2005 Botswana Global School-Based Health Survey <i>Patti Herring, Seter Siziya, Sricharan Pasupulati, Emmanuel Rudatsikira and Adamson S Muula</i>	1829
Chapter 105	Bullying Behaviour Following Students' Transition to a Secondary Boarding School Context <i>Leanne Lester and Donna Cross</i>	1837
Chapter 106	Bullying, Cyberbullying, Depression and Suicide Ideation <i>Yonatan Shpiegel, Anat Brunstein Klomek and Alan Apter</i>	1849

VOLUME 6

Chapter 107	Addressing Bullying of Student Nurses on Clinical Placements: The ARRC Resolution Model <i>Melanie Birks, Lea M Budden, Tanya Park, Tracey Simes and Tracy Bagley</i>	1859

Chapter 114	Victims of School Bullying: Predictors and Outcomes <i>Militsa Nikiforou and Panayiotis Stavrinides</i>	2099
Chapter 115	Bullying Victimization in Benin: Prevalence and Its Correlates among In-School Adolescents <i>Mazyanga L Mazaba-Liwewe, Sricharan Pasupulati, Emmanuel Rudatsikira, Olusegun Babaniyi, Idah Ndumba, Freddie Masaninga, Adamson S Muula, Peter Songolo and Seter Siziya</i>	2111
Chapter 116	Bullying Behaviour Following Students' Transition to a Secondary Boarding School Context <i>Leanne Lester, David J Mander and Donna Cross</i>	2123
Chapter 117	Bullying, Cyberbullying, Depression and Suicide Ideation among Youth: Comparing Online to Paper-and-Pencil Questionnaires <i>Yonatan Shpiegel, Anat Brunstein Klomek and Alan Apter</i>	2135
Chapter 118	Bullying: Parenting Styles in Victims and Aggressors <i>Maite Garaigordobil</i>	2145
Chapter 119	Homophobic Bullying: An Old Problem Only Recently Brought to Light <i>Paz Elipe and Rosario del Rey</i>	2161
Chapter 120	The Role of Attachment Styles in the Development of Aggressive Behavior Among Peers: An Overview on Homophobic Bullying with a Victim's Report <i>Giulio D'Urso, Irene Petruccelli, Adriano Schimmenti and Ugo Pace</i>	2175
Chapter 121	Suicidal Behavior in Association with in-School Bullying in African American Youth <i>Rhyanne S. McDade, Keith A. King, Rebecca A. Vidourek and Ashley L. Merianos</i>	2187

Chapter 122	Biopsychosocial Differential Predictors of Suicide and Bullying <i>Andrea D. Mata, Lacey E. Grogan and Caitlin Shellenbarger</i>	2197
Chapter 123	Modeling Bullying Propagation in Greece <i>Elena de la Poza, Lucas Jódar and Konstantina Marga</i>	2215
Chapter 124	Addressing the Problems of Bullying in Schools in the United Arab Emirates <i>Ken Rigby, Dalia Haroun and Essam Ali</i>	2225
Chapter 125	Homophobic and Sexual Minority Bullying: Research, Education and the Future <i>James O'Higgins Norman and Mairéad Foody</i>	2243

VOLUME 7

Chapter 126	Individual Level of Predictors of Face to Face Bullying: The Findings of a Two-Wave Longitudinal Study <i>Fatih Bayraktar</i>	2255
Chapter 127	Experiences and Meanings of Bullying Among Bullies, Victims, and Bystanders in an All-Girls School <i>Merimee Tampus-Siena</i>	2273
Chapter 128	Parents' Perceptions about Bullying <i>Eleni N. Nikolaou and Panagiotis J. Stamatis</i>	2289
Chapter 129	Bullying or Peer Abuse <i>Hugo Juárez Olguín, Arturo Loredó Abdalá and Miroslava Lindoro Silva</i>	2303
Chapter 130	Conceptualization of Anti-Bullying Strategies: Key Aspects in Every Curriculum Area <i>N. P. Mudzielwana</i>	2321
Chapter 131	Cyber Bullying Participation Roles: Examining the Relationship between Empathy and Psychopathy <i>Jessie L. Krienert and Jeffrey A. Walsh</i>	2337
Chapter 132	Aggression as a Developmental Disorder: From Bullying to Adult Delinquency <i>Gentian Vyshka and Admir Sinamati</i>	2359
Chapter 133	Peer Assault: Problems Associated with Bullying <i>Caleb McCoy, Brian Johnson, Yinan Zhao, Emily Salyer and Cliff McKinney</i>	2377
Chapter 134	Sexual, Physical and Psychological Aggression Linked to New Means of Communication: Child Pornography, Cyber-Grooming and Cyber-Bullying <i>Sébastien Prat and Carol Jonas</i>	2391

Chapter 135	From the Trenches: Cyberbullying and Beyond <i>Conor Mc Guckin and Lucie Corcoran</i>	2409
Chapter 136	How Research on Cyberbullying Has Developed <i>Peter K. Smith and Fethi Berkkun</i>	2419
Chapter 137	Conceptual and Definitional Issues Regarding Cyberbullying: A Case for Using the Term Cyber Aggression? <i>Pauline K. Hyland, John M. Hyland and Christopher Alan Lewis</i>	2437
Chapter 138	Prevalence Rates of Cyberbullying from a Cross-National Perspective: Definitional and Methodological Issues <i>Irene Connolly</i>	2459
Chapter 139	Cyberbullying among Children and Adolescents: A Quantitative and a Qualitative Approach to Gender Differences <i>Raúl Navarro, Santiago Yubero and Elisa Larrañaga</i>	2477
Chapter 140	Re-Thinking Well-Being Measures in Bullying and Cyberbullying Research <i>Jolanta Burke and Stephen James Minton</i>	2499
Chapter 141	Physical Proximity, Social Distance and Cyberbullying Research <i>Stephen James Minton</i>	2513
Chapter 142	The EU Kids Online Project: The Importance of Large Scale Cross-National Research <i>Brian O'Neill and Thuy Dinh</i>	2527
Chapter 143	Cyberbullying in South Korea <i>Seung-Ha Lee</i>	2543
Chapter 144	Needs, Determinants, Coping and Stand-Alone Interventions <i>Francine Dehue, Tijnje Völlink and Nicole Gunther</i>	2559
Chapter 145	Coping with Cyberbullying <i>Lucie Corcoran and Conor Mc Guckin</i>	2579
Chapter 146	Cyberbullying and Mental Health: Internet-Based Interventions for Children and Young People <i>Nicole Gunther, Francine Dehue and Viviane Thewissen</i>	2597
Chapter 147	The Australian Perspective: Efforts to Counter Cyberbullying <i>Marilyn Campbell</i>	2609
Chapter 148	Teachers' Perceptions of Cyberbullying in Irish Secondary Schools <i>Caroline Wheeler</i>	2627
Chapter 149	Concluding Thoughts: Where Are We Now and Where to Next? <i>Lucie Corcoran</i>	2645
Index		2659

PREFACE

This 7 volume set is a compilation of important research on bullying. Some of the topics addressed include:

- cyberbullying, a form of bullying carried out using electronic communication
- violent behavior
- homophobia and its role in bullying
- bullying prevention programs
- predictors of school bullying
- coping strategies and efforts to counter bullying behavior

Chapter 1

A SOCIAL-ECOLOGICAL APPROACH TO UNDERSTANDING CYBERBULLYING INVOLVEMENT

Michelle F. Wright*, PhD

Faculty of Social Studies, Department of Psychology,
Institute for Research on Children, Youth and Family,
Masaryk University, Brno, the Czech Republic

INTRODUCTION

Nowadays, children and adolescents are enmeshed in an increasingly digitally connected global community. Many scarcely remember a time in which their lives were not in some way connected to information and communication technologies (ICTs). Their usage of ICTs has led to many conveniences in their lives, such as the ability to rapidly communicate with friends and families and having access to almost an infinite amount of information at their fingertips. A dark side to children's and adolescents' ICT usage is cyberbullying. Defined as an extension of traditional face-to-face bullying, cyberbullying involves bullying behaviors utilizing ICTs, including email, instant messaging, social networking sites, and text messages, to intentionally harm a target or targets (Grigg 2010; Grigg 2012; Nocentini et al., 2010). This chapter reviews the social-ecological approach, discusses the theory in relation to traditional face-to-face bullying, and applies the theory to the study of cyberbullying.

THE SOCIAL-ECOLOGICAL APPROACH

Bronfenbrenner's (1977; 1979) ecological theory of development conceptualizes of various overlapping systems which directly and indirectly impact human behaviors. The theory was developed in response to Bronfenbrenner's criticism that theories at the time (1970s) were restricted. His theory included two propositions that define various properties of the model. For Proposition 1, Bronfenbrenner explained that human development takes place through

* Corresponding Author's Email: michelle.wright@mail.muni.cz.

reciprocal and frequent interactions between a human and his or her immediate environment, referred to as proximal processes. Proposition 2 suggests that “the form, power, content, and direction of the proximal processes effecting development vary systematically as a joint function of the characteristics of the developing person; of the environment – both immediate and most remote – in which the processes are taking place; and the nature of the developmental outcomes under consideration” (Bronfenbrenner 1994 p. 38). To illustrate Propositions 1 and 2, Bronfenbrenner gives an example from Drillien’s (1963) longitudinal study on the factors influencing the development of children who were born with low birth weight and those of normal birth weight. Finding revealed that mother-child interactions over the course of 4 years was the strongest predictor of developmental outcomes as it reduced behavioral disturbances (Proposition 1). This relationship varied as a function of the environmental context, specifically social class in this study, and birth weight (an individual characteristic) (Proposition 2).

Figure 1. Bronfenbrenner’s Social-Ecological Theory.

Utilizing Lewin’s theory of psychology fields (1935), Bronfenbrenner (1977) proposed that the ecological environment includes nested structures, each within each other, moving from the innermost level (i.e., the individual) to the outside (see Figure 1 for a visual conceptualization of the Bronfenbrenner’s social-ecological theory). The first level is the microsystem. The microsystem is defined as the activities, social roles, and interpersonal

relationships of a person. Examples of microsystems include family, school, peer group, and workplace. The next level is the mesosystem which includes the linkages and interactions among two or more settings in a person's life. In particular, the mesosystem is the interaction across various systems, such as the effects of the relationships between home and school. The exosystem includes the linkages and processes that occur between two or more settings that do not directly involve the person. Instead, the relationship between these settings has an indirect influence, such as the relationship between the home and the parent's workplace. Consisting of the microsystem, mesosystem, and exosystem, the macrosystem represents the characteristics of a given culture or subculture. Bronfenbrenner conceptualizes of the macrosystem as a "societal blueprint" (p. 40). The final system is the chronosystem. This system includes change or consistency over time in a person's life. An example of the chronosystem might include changes over time in the family structure or socioeconomic status.

APPLICATION OF THE SOCIAL-ECOLOGICAL THEORY TO TRADITIONAL FACE-TO-FACE BULLYING

Researchers (e.g., Barbarino & deLara 2002; Swearer & Espelage 2004) have written extensively on the application of Bronfenbrenner's social-ecological theory to traditional face-to-face bullying. They argue that bullying does not occur in isolation and that instead these behaviors are promoted or inhibited through a complex interaction among the person, family, peer group, school, community, and culture. The person is at the center of the systems, and he or she is affected by each system, which thereby impacts the person's behavior.

Ample research has documented the individual influences on bullying perpetration and victimization. This literature has identified psychopathic tendencies, the endorsement of masculine traits, conduct problems, callous-unemotional traits, the hostile attribution bias, antisocial personality traits, susceptibility to peer pressure, depression, and social status as individual-level predictors of bullying (Fanti & Kimonis 2012; Ferguson, San Miguel & Hartley 2009; Kaltiala-Heino, Rimpela, Rantanen & Rimpela 2000; Li & Wright 2014).

Different microsystems also have a role in bullying. For instance, various family characteristics, such as family members' involvement in gangs, poor parental supervision, negative family environment, parental conflict, low parental communication, parental abuse, and authoritarian parenting are linked to bullying (Baldry 2003; Espelage, Bosworth, & Simon 2000; Espelage & Swearer 2010; Pepler, Jiang, Craig & Connolly 2009). Peers also influence children's and adolescents' involvement in bullying. Higher levels of peer conflicts, peer norms that support bullying, and affiliation with aggressive peers have roles in bullying involvement (Craig & Pepler 1997; Espelage, Holt & Henkel 2003; Pepler et al., 2010). The school context also impacts bullying and victimization such that negative school climate, inappropriate teacher responses to bullying, poor teacher-student relationships, and low levels of teacher support promote bullying among children and adolescents (Bauman & Del Rio 2006; Gendron, Williams & Guerra 2011; Richard, Schneider & Mallett 2011). Communities and cultural factors also influence bullying, including living in unsafe neighborhoods, poverty, and exposure to violent TV and video games (Bradshaw, Sawyer, & O'Brennan 2009; Chaux, Molano & Podlesky 2009; Janssen, Boyce & Picket 2012; White & Mason 2012). Swearer and

Hymel (2015) also suggested that bullying and victimization occur more often in communities in which violence is modeled.

EXPANSION OF THE SOCIAL-ECOLOGICAL THEORY TO INCLUDE ICTs AND THE CYBER CONTEXT

With the increasing prominence of ICTs and the internet in children's and adolescents' lives, cyberbullying has become a growing concern. Theoretical conceptualizations of cyberbullying have been slow to develop. In this book, Barlett (Chapter 2) reviews various theoretical frameworks used to understand cyberbullying. Some of these include the General Strain Theory and the General Aggression Model. Similarly, den Hamer and Konijn (Chapter 13) created their own theory, the Cyclic Process Model, to explain cyberbullying perpetration. Each of these theories are great for explaining individual-level predictors of cyberbullying involvement, although den Hamer and Konijn incorporate exposure to risky media content in their model, which is considered an exosystem level predictor. Much of the research on cyberbullying involves the role of individual-level predictors, despite some attention having been given to the microsystem (i.e., schools, peers, parents), the mesosystem (i.e., school and peer interactions), and the exosystem (i.e., exposure to violent media content). In this book, many of the chapters are focused on individual-level predictors (see Chapters 5 through 9), with Chapter 10 describing the family context, Chapter 11 the peer context, Chapter 12 the school context, and Chapter 13 risky media content. Therefore, the social-ecological perspective might provide a framework for understanding children's and adolescents' involvement in cyberbullying. Below is a hypothesized revision to Bronfenbrenner's social-ecological theory (see Figure 2). It is important to note that this model involves cyberbullying specifically. However, the model should be expanded to include other risks and opportunities associated with ICT and internet usage among children and adolescents.

Like Bronfenbrenner's social-ecological theory, the version applied to cyberbullying also includes individual-level predictors, the microsystem, the mesosystem, the exosystem, the macrosystem, and the chronosystem. These systems are discussed below with literature supporting the role of a particular system in cyberbullying.

Person Level

Researchers have focused a lot of their attention on the characteristics and risk factors associated with children's and adolescents' involvement in cyberbullying. Age and gender have been frequently examined, with inconsistent findings (e.g., Boulton, Lloyd, Down & Marx 2012; Li 2007; Wade & Beran 2011; Ybarra, Diener-West & Leaf 2007). These findings are further discussed in Chapters 5 through 7. Various studies have revealed that cyberbullying perpetration is related to traditional face-to-face bullying perpetration, that cyber victimization is associated with traditional face-to-face victimization, and that traditional face-to-face victimization is linked to cyberbullying perpetration (Barlett & Gentile 2012; Cappadocia, Craig & Pepler 2013; Corcoran, Connolly & O'Moore 2012; Heirman & Walrave 2012; Mitchell, Ybarra & Finkelhor 2007; Steffgen, Konig, Pfetsch & Melzer 2011). Higher levels of

electronic technology usage is related to cyberbullying perpetration and victimization (Aricak, Siyahhan, Uzunhasanoglu, Saribeyoglu, Ciplak, Yilmaz & Memmedov 2008; Ybarra et al., 2007). Furthermore, internalizing difficulties, like depression and loneliness, and externalizing difficulties, like alcohol and drug use and violence, are risk factors for cyberbullying involvement (Cappadocia et al., 2013; Mitchell et al., 2007; Ybarra & Mitchell 2004). Greater levels of normative beliefs concerning face-to-face bullying and cyberbullying predict cyberbullying perpetration (Ang, Tan, & Mansor 2010; Burton, Florell & Wygant 2013; Wright & Li 2013a). Lower levels of provictim attitudes, less self-control and empathy, callous-unemotional traits, and greater moral disengagement are also related to cyberbullying (Fanti et al., 2012; Steffgen et al., 2011; Wright, Kamble, Lei, Li, Aoyama & Shruti 2015). Peer rejection and perceived popularity also relate positively to cyberbullying perpetration and cyber victimization (Sevcikova, Machackova, Wright, Dedkova & Cerna 2015; Wright & Li 2013b; Wright 2014).

Figure 2. Conceptualization of Bronfenbrenner's Social-Ecological Theory.

Microsystem

Like traditional face-to-face bullying, the microsystem includes family, parents, and peers. Indifferent-uninvolved parenting styles and inconsistent monitoring of face-to-face and online activities increases children's and adolescents' risk of cyberbullying involvement (Aoyama, Utsumi & Hasegawa 2011; Dehue, Bolman, Vollink & Pouwelse 2012; Mesch 2009; Navarro, Serna, Martinez & Ruiz-Oliva 2013; Wright 2015). In addition, cyberbullying involvement was associated with family characteristics, such as poor caregiver monitoring, and poor emotional bonds with caregivers (Ybarra & Mitchell 2004). Many school administrators and teachers do not perceive cyberbullying as problematic, which increases the likelihood of cyberbullying involvement among children and adolescents (Sahin 2010). Similarly, teachers' unfamiliarity with cyberbullying increases cyberbullying involvement (Cassidy, Brown & Jackson 2012). Students who perceive their school and teachers less positively are more likely to be perpetrators and victims of cyberbullying (Bayar & Ucanok 2012). Cyberbullying involvement inhibits children's and adolescents' academic attainment and performance (Eden, Heirman & Olenik-Shemesh 2013; Wright in press). Lower school commitment and perceptions of a negative school climate increase children's and adolescents' cyberbullying perpetration as they feel less connected to their school (Williams & Guerra 2007). In one study, the best predictor of cyberbullying involvement was the level of cyberbullying perpetration and victimization in students' classrooms (Festl, Schwarkow & Quandt 2013). Lower levels of peer attachment and high peer norms for bullying also predict cyberbullying perpetration (Hinduja & Patchin 2013; Wright et al., 2015). Additional details regarding microsystems applied to cyberbullying are provided in Chapter 10 concerning the family context, Chapter 11 for the peer context, and Chapter 12 for the school context.

Mesosystem

The Meosystem includes interactions among various systems. Little attention has been given to the connection between the systems and how they influence children's and adolescents' cyberbullying. In one study, Arslan et al. (2012) found that parental unemployment predicted cyberbullying perpetration. Although Arslan and colleagues did not specifically connect parental unemployment to the mesosystem, it might be likely that conflict from the parent's workplace impact the family environment, which thereby contributes to cyberbullying. Another possible link between two systems that impact cyberbullying might be the interaction between neighborhood peers and schools. In particular, Pendergrass and Wright (Chapter 23) describe various case studies of cyberbullying victims, and they outlined how the cases connect to various systems in the Social-Ecological Theory. One such connection they made was between peers outside of one's school and peers within one's school. They found that many cyberbullying incidences occurred outside of school, involving peers in victims' immediate surrounding. However, these peers did not necessarily attend the same school as the victims. After the cyberbullying experience, the knowledge of the event and further perpetration of the cyberbullying incident occurred in the school environment, suggesting a connection between neighborhood level variables and the school context. Such a proposal is concerning as it suggests a "spillover" effect of out-of-school cyberbullying to in-school bullying and cyberbullying.

Exosystem

In Chapter 13, den Hamer and Konijn discuss the role of adolescents' exposure to risky behavior through media in cyberbullying perpetration. Their empirical research indicated a relationship among this exposure and cyberbullying perpetration among adolescents (den Hamer, Konijn & Keijer 2014; den Hamer & Konijn 2015). Other research by Fanti and colleagues (2012) also suggested that children's and adolescents' exposure to violent media content longitudinally predicted cyberbullying involvement one year later. Pendergrass and Wright (Chapter 23) explained that many cyberbullying laws were initiated by parents who had a child who was affected by cyberbullying victimization. They indicated that such laws represent an exosystem as the expectation is that these laws will deter children and adolescents from perpetrating cyberbullying.

Macrosystem

Although the literature on the association between the beliefs of different cultural groups and cyberbullying involvement is scarce, there is research which reveals that cyberbullying occurs among multiple countries. This literature is reviewed in this book and includes research in the Mediterranean region (Chapter 15), Asian countries (Chapter 16), various European countries (Chapter 17), and ethnic groups in the United States (Chapter 18). Cross-cultural examinations are still developing in the area of cyberbullying. For instance, children and adolescents in the United States self-reported higher levels of cyberbullying perpetration and cyber victimization when compared to Japanese children and adolescents (Aoyama et al., 2011; Barlett, Gentile, Anderson, Suzuki, Sakamoto, Yamaoka & Katsura 2013). Similar patterns were found when Japanese children and adolescents were compared to Austrian children and adolescents (Strohmeier, Aoyama, Gradinger & Toda 2013). In addition, Li (2008) found that Chinese children and adolescents engaged in less cyberbullying perpetration when compared to Canadian children and adolescents. Such findings might indicate that individualism and collectivism have a role in cyberbullying involvement. However, caution should be given to this proposal as Li (2006) found in another study that Chinese adolescents were more often the victims of cyberbullying and Shapka and Law (2013) found that East Asians adolescents perpetrated higher levels of proactive cyberbullying when compared to Canadian adolescents.

Chronosystem

Research on the chronosystem has been slow to develop. However, this is a ripe area for investigation. There have been rapid changes in the access to and frequency of technology use over the last decades. Children and adolescents have access to technology at home, at their school, and with their peers. They have many opportunities to connect and interact online and through technologies. Technology is rapidly evolving and consequently so are the tools used to cyberbully others. Ten years ago, textual forms of cyberbullying, like through email and chatrooms, were frequently utilized. Nowadays, video forms of cyberbullying are becoming more common than they were years ago. In addition, mobile phones have a variety of functionality when it comes to technology usage in which children and adolescents can view

videos, check social networking sites, send text messages, and access the internet. The multifunctionality of these devices might make it easier for children and adolescents to cyberbully their peers. Another component of the online environment is the potential for disinhibited behaviors. When interacting with others online, people are removed from each other and receive limited feedback. The potential for anonymity allows individuals to say things and behave in different ways in the online environment than they would offline, which can increase the likelihood of cyberbullying (Suler 2005). There is literature linking greater beliefs in the potential to remain anonymous online to cyberbullying behaviors (Wright 2014).

CONCLUSION

Taken together, research has focused on some components of the social-ecological theory as applied to cyberbullying. The proposed theoretical model in Figure 2 suggests that various contexts exist that affect children's and adolescents' cyberbullying involvement. It is clear that the family, school, and peer contexts have a role in online behaviors. The roles of the mesosystem, exosystem, macrosystem, and exosystem are less understood in the cyberbullying literature. The proposed reconceptualization of the social-ecological approach suggests that there are complex interactions among various factors which contribute to cyberbullying. A discussion of future research and prevention and intervention programs was neglected from this particular chapter as these will be discussed later in this book.

Chapter 2

PAST, PRESENT, AND FUTURE THEORETICAL DEVELOPMENTS IN PREDICTING CYBERBULLYING BEHAVIOR

Christopher P. Barlett*, PhD

Gettysburg College, Department of Psychology, Gettysburg, PA, US

INTRODUCTION

Theory is an integral part of the scientific method that allows researchers to make informed hypotheses while delineating the mediating and moderating mechanisms to describe why, when, and for whom a relationship is likely to occur. Collected data are the means by which theoretical arguments are supported or refuted. Overall, in order to advance our understanding of scientific effects, theory must be utilized, tested, re-tested, and reformed (if necessary); however, the literature examining cyberbullying perpetration (defined as "...any behavior performed through electronic or digital media by individuals or groups that repeatedly communicates hostile or aggressive messages intended to inflict harm or discomfort on others" [Tokunga 2010, pg. 278]) is only just beginning to appropriately apply theory. To aid researchers in this endeavor, the current chapter will attempt to summarize several prominent theories that have been recently applied to predicting cyberbullying behavior. This chapter will only focus on theory as applied to cyberbullying perpetration. There have been myriad theoretical advances in our understanding of the predictors and consequences of cyber-victimization. First, I will present some early cyberbullying work that laid the groundwork for our current understanding of cyberbullying behavior. Then, I will describe several theories and research that has been recently applied to cyberbullying perpetration effects (including strengths and limitations). Finally, I will conclude with future directions and applied extensions.

PAST: THE GROUNDWORK

When cyberbullying research was in its infancy, the majority of research focused on determining (a) the psychological and behavioral consequences to the victim, (b) establishing the relative frequencies that various samples engage in cyberbullying behavior (e.g., cyberbullying only, cyber-victimization only, cyberbullying-victimization, or not involved), and (c) testing gender and age (grade) effects in these frequencies. Such research is incredibly important for establishing the scope of a new burgeoning societal issue and these results are often needed prior to delving into the theoretical landscapes that may offer explanations about why individuals engage in cyberbullying behaviors.

The research questions and data were helpful in studying cyberbullying perpetration scientifically. General trends and frequencies suggested that the majority of participants report not engaging in cyberbullying behaviors. For instance, Ybarra and Mitchell (2004) sampled 1,498 youth and found that 11.73% were classified as cyberbullies only, 3.66% were cybervictims only, 2.86% were cyberbully-victims, and 81.55% were uninvolved; trends found in similar studies (e.g., Bauman 2010; Aricak et al., 2009). Additional descriptive studies found evidence to suggest that cyberbullying was less prevalent than cyber-victimization. Indeed, DeHue, Bolman, and Vollink (2008) found that 16% of youth reported engaging in cyberbullying and 22% reported cybervictimization, a finding that was generally reliable among other studies (e.g., Hinduja & Patchin 2008; Li 2007). Although non-theoretical, these findings showed the scientific community and general population that cyberbullying was a societal issue that necessitated additional study. Moreover, despite the overwhelming finding that youth tend to be uninvolved, the percentage of individuals who engaged in cyberbullying and/or were cybervictimized was not trivial. One limitation of studying prevalence rates is that the frequencies that youth report being cyberbullied, cybervictimized, or both largely depend on several methodological differences making comparisons across studies unwarranted. Rivers and Noret (2009) argued that definitional, measurement, age, gender proportion, and sampling differences may account for such variation.

In addition to testing the relative frequencies of involvement, other research tested gender and age effects in cyberbullying frequency. In my opinion, this was an incredibly important research endeavor that aimed to identify variables that increased the likelihood of cyberbullying perpetration. Although this research did not typically assess mediating mechanisms, identifying the risk factors of cyberbullying perpetration was paramount of understanding this form of aggression. Regarding gender effects, results tended to show negligible differences between males and females in cyberbullying (e.g., Beran & Li 2007; Bauman 2010; Hinduja & Patchin 2008). However, in a recent meta-analysis, Barlett and Coyne (2014) found this effect to be moderated by age: males tended to cyberbully more than females at older ages (e.g., during emerging adulthood), whereas females were more likely to cyberbully compared to males at younger ages (late childhood), while no gender differences occurred during middle adolescence. Regarding age effects, Kowalski and Limber (2007) revealed that younger kids (6th graders) were less likely to be involved in cyberbullying compared to their 7th or 8th grade peers. Similar age effects were found by Ybarra and Mitchell (2004) who showed that youth between 15-17 years old were more likely to cyberbully relative to their younger peers (aged 10-14).

Overall, the nature of the early cyberbullying research was insightful and answered important research questions while also propelling the issues regarding cyberbullying to the general public. Please note that I consider such studies important for our current understanding of cyberbullying perpetration and current research is still interested in age and sex effects while also examining the frequencies by which youth cyberbully. I classified the cited work as “early” because of the lack of emphasis on theory development not because of the quality of the work itself.

PRESENT: THE USE OF THEORY

While the early research laid the groundwork for quantifying cyberbullying perpetration and testing simple relationships, the field slowly started to shift to applying and developing theoretical arguments regarding the psychological processes to explain cyberbullying behavior. I do not present an exhaustive list of all possible theories that have been used to explain cyberbullying perpetration behavior. Rather, I will discuss several theories that have clear application to the cyberbullying literature and discuss the strengths and limitations of each while delving into the research testing several important theoretical postulates.

Theory of Reasoned Action

Derived from social psychological theory, the Theory of Reasoned Action (Ajzen & Fishbein 1980; Fishbein & Ajzen 1975) detailed the psychological processes used to predict human behavior while focusing on the literature showing how attitudes can predict behavior. Briefly, the Theory of Reasoned Action predicts that attitudes and subjective norms indirectly predict behavior through behavioral intent (defined as the motivations behind a given behavior; see Hale, Householder, & Greene 2002). This theory has received a wealth of research support by predicting myriad health behaviors including mammography participation (e.g., Montano & Taplin 1991), AIDS-preventive behavior (e.g., Fisher, Fisher, & Rye 1995), and mother’s choice to breast feed (e.g., Manstead, Proffitt, & Smart 1983) amongst others. Beyond health behaviors, the Theory of Reasoned Action has also been applied to social behaviors, such as traditional bullying. Rigby (2005) sampled 400 Australian youth and found that bullying behavior was positively related to unsympathetic attitudes towards the victim (attitudes) and the belief that their friends were supportive of their bullying behaviors (subjective norms). Other researchers have found similar effects in the traditional bullying domain (e.g., Salmivalli & Voeten 2004), suggesting that attitudes and subjective norms for behavior are important predictors of bullying behavior.

The application of the Theory of Reasoned Action to cyberbullying is intuitive. Doane, Pearson, and Kelley (2014) measured three types of cyberbullying behavior (online deception, online malice, and online public humiliation), cyberbullying attitudes, norms for cyberbullying, and cyberbullying intention in a sample of US college students. Using path modeling procedures, results showed strong relations between the measured variables. For instance, results showed that cyberbullying attitudes predicted cyberbullying intentions, which predicted all three types of subsequent cyberbullying behavior. Further, depending on the type of

cyberbullying measured, the Theory of Reasoned Action predicted between 54%-63% of the variance in cyberbullying behaviors. In support of the relation between subjective norms, Barlett and Gentile (2012; Study 2) found that positive reinforcement from family and friends regarding cyberbullying tactics positively predicted cyberbullying behavior.

There are numerous strengths to applying the Theory of Reasoned Action to cyberbullying effects. First, there is a strong psychological history utilizing this theory, allowing for researchers to draw on an abundance of literature and theoretical trial and error to make empirical hypotheses. Second, Theory of Reasoned Action has strong face validity in the cyberbullying world. The extent to which cyberbullying intent predicts cyberbullying behavior and how both cyberbullying attitudes and norms are indirectly related to cyberbullying perpetration through intent has received research support (e.g., Doane et al., 2014; Barlett & Gentile 2012).

However, there are some limitations that warrant consideration and future work. First, Olweus (2012) argued that cyberbullying is another form of traditional bullying and supported his claim by showing that the frequencies of cyber-victimization are lower than that of traditional bullying victimization. Findings from Olweus (2012) suggest a very important theoretical question: What does applying Theory of Reasoned Action to cyberbullying offer beyond what we already know from the traditional bullying domain? In other words, would the correlations between attitudes, norms, intent, and behavior be the same for either type of bullying? These are important questions, and, unfortunately, this is an empirical question that has yet to be answered. It is important that a theoretical model that is supposed to uniquely predict cyberbullying behavior to either show incremental validity beyond the traditional bullying world or statistically control for the correlation between cyber and traditional bullying behaviors in their analyses. Indeed, Barlett and Gentile (2012) found that traditional and cyberbullying frequency correlate significantly with each other, but also both correlate to positive attitudes specific to cyberbullying. Therefore, one must question whether the model and results shown by Doane et al. (2014) would have been similar if the cyberbullying measures were replaced with traditional bullying measures. If the model has incremental validity then it should predict (i.e., fit better) cyberbullying better than traditional bullying, but such evidence has eluded researchers.

Second, longitudinal research testing the variables included in the Theory of Reasoned Action is needed in order to make causal claims. An ideal longitudinal study would involve testing cyberbullying attitudes and norms at Wave 1, intent at Wave 2, and cyberbullying behavior at Wave 3 in order to show the predicted mediated effect. Barlett, Gentile, and Chew (in press) used a four wave longitudinal study and found evidence to suggest that cyberbullying attitudes and cyberbullying behavior were fairly stable over time and were correlated. However, intent, norms, and face-to-face bullying were never measured.

General Strain Theory

General Strain Theory (Agnew 1992; 2009) posits that stressors (strains) in one's life will increase negative affect, and in order to emotionally regulate the negative affect and psychologically overcome the negative influence of the strains, one will often rely on aggressive and criminological behaviors. General Strain Theory has received strong empirical support in both the traditional (Hay & Meldrum 2010) and cyberbullying domains (Patchin &

Hinduja 2011). Applying General Strain Theory to predicting cyberbullying necessitates first asking what strains exist that can push youth to engage in cyberbullying behavior in order to feel better. One possible strain that has received empirical attention is being victimized. According to General Strain Theory, being cyber-victimized is a strain that will increase negative feelings, such as anger (e.g., Beran & Li 2005), depression (e.g., Patchin & Hinduja 2006), suicide ideation (e.g., Hinduja & Patchin 2010), and anxiety (e.g., Beran & Li 2005). Support for this theory would also show that cyber-victimization and traditional victimization predict cyberbullying behavior. Bonanno and Hymel (2013) found significant correlations between cyberbullying perpetration and traditional victimization ($r = .12$), verbal victimization ($r = .15$), social victimization ($r = .14$), and cyber-victimization ($r = .39$), supporting General Strain Theory.

The General Strain Theory offers a complete theoretical explanation regarding the complex relations between cyberbullying, traditional bullying, victimization, and cyber-victimization frequencies. Further, this parsimonious model also elucidates the mediating principles that govern these relations. Recall that General Strain Theory predicts that if one is victimized (or possibly other strains) that should predict negative affect and emotions (Agnew 2001), which may cause an increase in cyberbullying behaviors. Therefore, being initially victimized can explain future cyberbullying behavior due to the retaliatory nature of feeling psychologically hurt.

Additionally, research in the cyberbullying world often shows these aforementioned relations while controlling for other possible strains. For instance, Hay, Meldrum, and Mann (2010) found that cyberbullying victimization was significantly correlated with negative psychological outcomes (e.g., delinquency and suicide ideation) while controlling for other possible strains and variables predictive of strain, such as gender, parental control, ethnicity, poor school grades, and time with peers. Additionally, Jang, Song, and Kim (2014) replicated this finding while controlling for additional strains, such as financial strain, parental strain, and others.

However, limitations exist when applying this model to the cyberbullying world that necessitates future work. The first is that the research applying General Strain Theory to cyberbullying effects only controls for additional strains, but perhaps the interactive effect of cyber-victimization and another strain should be tested. For instance, Fanti, Demetriou, and Hawa (2012) found that negative family and friend social support at Wave 1 significantly predicted cyberbullying frequency at Wave 2 (one year later). General Strain Theory would posit that such negative family and friend support are two strains that may interactively predict cyberbullying behavior; however, such interactions were not reported.

A second limitation mirrors that of the discussion of The Theory of Reasoned Action in the inability to theoretically separate cyber from traditional bullying frequencies. For instance, Hay et al. (2010) did not test a model in which the effect of strains on cyberbullying (see previous paragraphs) remained while controlling for traditional bullying. Further, if the research that distinguishes bullies, victims, and bully-victims is valid, then this latter group (those who are both bullied and bully others) should experience the most strain, thereby, experiencing the most negative affective consequences. Finally, work is needed to further test the General Strain Theory that assesses negative emotions longitudinally in order to test for mediation.

Barlett and Gentile Cyberbullying Model

The Barlett and Gentile Cyberbullying Model (BGCM; Barlett & Gentile 2012) was derived from the research detailing the differences in cyber vs. traditional bullying perpetration. Namely, Vanderbosh and Van Cleemput (2008) argued that due to the online nature of cyberbullying, cyberbullies likely feel more anonymous online, should have less concern about the power differential prominent in the traditional bullying world, and cannot use physical methods to cause harm online. Drawing upon broader learning theories, such as the General Learning Model (Gentile et al., 2009), Barlett and Gentile (2012) posited that after a cyber-attack, the aggressor is likely to learn that they are anonymous (and likely not going to get caught) and that the concern over the traditional strength differential is removed. Barlett et al. (in press) clearly point out that anonymity and lack of concern about the strength differential are neither necessary nor sufficient conditions for cyberbullying behavior. One can spread rumors, for example, about another in the real world (i.e., not online) in an anonymous way. Further, an individual may know their cyber-aggressor. However, Barlett and colleagues have suggested that it is the *perceived* anonymity that can influence cyberbullying behavior. Once learned and automatized with subsequent cyber-aggressive acts, these constructs are likely to lead to the development of positive attitudes toward cyberbullying, which will predict subsequent cyberbullying behavior. This model is cyclical in the sense that continued cyberbullying behaviors will further reinforce the anonymity and lack of concern about the strength differential constructs to predict the frequency of later cyberbullying behavior through the aforementioned mediated processes via positive attitudes toward cyberbullying.

In their initial paper, Barlett and Gentile (2012) used a correlational research design sampling US college students and found (a) the correlation between cyberbullying attitudes and behavior was positive and significant, (b) perceived anonymity and lack of concern about strength differential were positively correlated with cyberbullying behavior and attitudes, and (c) positive attitudes toward cyberbullying mediated the relation between lack of concern about the strength differential cyberbullying behavior and the between anonymity and cyberbullying behavior. Since these initial findings, the BGCM has received additional empirical support using longitudinal designs while sampling myriad populations. For instance, Barlett (2015) used a four-wave longitudinal design with US adolescents and found that anonymity and cyberbullying attitudes at Wave 1 accounted for a significant proportion of the variance in cyberbullying frequency at Wave 4, approximately seven months later. This finding was further replicated by Barlett, Gentile, and Chew (in press) with a college-aged US sample. Furthermore, Barlett, Gentile, Anderson, Suzuki, Sakamoto, Yamaoka, and Katsura (2014) used a two-wave longitudinal design and found that Wave 1 cyberbullying attitudes significantly predicted Wave 2 cyberbullying behavior in both US and Japanese emerging adults approximately two months later.

One strength of the BGCM is the original derivation that clearly separated the traditional from the online bullying literature. As I have previously argued, this is a key limitation both Theory of Reasoned Action and General Strain Theory. Indeed, Barlett and Gentile (2012) showed that the relation between cyberbullying attitudes and cyberbullying behavior was stronger than the relation between cyberbullying attitudes and traditional bullying frequency, despite the strong relation between both types of bullying behaviors. Even though this directly addresses the Olweus (2012) argument and suggests that although cyber and traditional bullying behaviors are correlated, they are psychologically different that can influence the

correlations between predictor variables and these antisocial outcomes, future work is still needed. None of the Barlett work has tested face-to-face bullying attitudes to see how such evaluations influence cyberbullying.

Second, the BGCM has been tested using both correlational (Barlett, in press) and longitudinal research designs (Barlett et al., in press). The longitudinal evidence is especially important for showing causal relations between the variables in the model, while the correlational findings offer support for the simple relations that have theoretical importance. If the same effect using different research designs and paradigms is found, that suggests that relations between the variables and the underlying theory are robust (Gentile et al., 2009).

However, limitations exist that necessitate future work when using the BGCM to predict cyberbullying perpetration. First, the measures used to assess anonymity, lack of concern about the strength differential, and cyberbullying attitudes have not shown consistent reliability across differing studies. For instance, Barlett and Gentile (2012) found that the anonymity scale to have an adequate internal consistency ($\alpha = .62$), whereas the same scale has had less than optimal internal consistency in other studies ($\alpha < .60$; Barlett et al., in press). These differences may be attributed to artifacts of data collection, such as differences in populations, but it could also represent the inherent issues in trying to capture attitudes towards antisocial behaviors that are constantly shifting with changes in technology. Another limitation is that the postulates of BGCM have only been tested using several short-term longitudinal studies or correlational research designs. A multi-wave longitudinal study utilizing long periods of time between data collection is desperately needed. In a related vein, not much research has focused on the lack of concern about strength differential postulate of the BGCM outside of the original Barlett and Gentile (2012) findings. Future work is needed to further test this tenant of the model. Finally, it is not likely that anonymity and lack of concern about the traditional strength differential are the only two learned exogenous variables that predict cyberbullying attitudes. For instance, Werner, Bumpus, and Rock (2010) found that time spent online predicted cyberbullying behaviors, which may be another exogenous variable in the BGCM. Overall, much more work is needed to continue to validate and test this model.

General Aggression Model

The General Aggression Model (GAM; Anderson & Bushman 2002) is a dynamic social-cognitive theory of aggression derived from myriad domain specific aggression theories (see Barlett & Anderson 2013; Anderson & Carnagey 2004; DeWall, Anderson & Bushman 2011 for extensive reviews). Briefly, GAM elucidates the psychological mechanisms related to the short-term predictors and long-term learning of aggressive behaviors. The proximate portion of GAM posits that two types of input factors, the situation (e.g., a provocation) and one's personality (e.g., trait aggression) will likely interact to influence the present internal state (consisting of inter-related aggressive affect, aggressive cognitions, and physiological arousal). Increases in any combination of the internal state variables will influence appraisal and decision making processes that predict an impulsive or premeditated aggressive or non-aggressive behavior.

Each successful cycle through the proximate GAM is one learning trial with an aggression related stimulus. With continued experiences and practice with aggression-related factors and processes, individuals are likely to learn about such relations. This continued reinforced

learning will lead to the development of various aggression-related knowledge structures, such as aggressive attitudes, aggressive scripts, desensitization, and others, which form one's aggressive personality. Additionally, extended learning and practice with aggression stimuli and the aggressive knowledge structures leads to the automatization of the activation of these knowledge structures that predict behavior (Anderson & Bushman 2002).

In perhaps the largest meta-analysis to date on cyberbullying predictors, Kowalski, Giumetti, Schroeder, and Lattanner (in press) applied the GAM to theoretically understand the myriad psychological, sociological, and personality variables that predict cyberbullying perpetration. In a creative application, Kowalski et al. (in press) argued that gender differences (Barlett & Coyne 2014), age differences (Kowalski et al., 2007), and technology use (Werner, Bumpus & Rock 2010) were personality factors that interacted with situational factors (e.g., perceived anonymity [Barlett 2015]) to influence one's internal state and subsequent appraisal and decision making processes to predict a cyberbullying encounter. In support of this theoretical application, the results from the Kowalski et al. (in press) meta-analysis of 1,365 studies (sampling over 400,000 participants) found that cyberbullying perpetration was significantly correlated with traditional bullying ($r = .45$), age ($r = .05$), frequency of Internet usage ($r = .20$), narcissism ($r = .22$), anger ($r = .20$), normative aggressive beliefs ($r = .37$), and moral disengagement ($r = .27$). According to GAM, these variables represent a wide array of learned personality input factors that positively predict a cyberbullying encounter.

The GAM has several strengths in regard to its theoretical power in predicting cyberbullying perpetration. First, unlike the previous theories discussed in this chapter, GAM is broad and has the ability to integrate several specific findings from the primary research into a cohesive theoretical umbrella. Second, GAM relies on learning postulates to delineate the psychological processes engaged in predicting why cyberbullies continue to harm others online. Indeed, if an individual attacks another online (and are positively reinforced for it), that is one learning trial that will likely get automatized if subsequent cyber-attacks occur. This alone can help explain the strong stability coefficients observed in longitudinal studies of cyberbullying behaviors (Fanti et al., 2012). Finally, GAM can take into account the combination of variables that are positively and negatively correlated with cyberbullying behavior, termed the risk and resiliency approach (see Barlett 2015). Indeed, Kowalski et al. (in press) also found that empathy ($r = -.12$), parental monitoring ($r = -.07$), and school safety ($r = -.13$) were negatively correlated with cyberbullying perpetration. The GAM would posit that cyberbullying is less likely to occur if an individual has more protective than risk factors related to cyberbullying perpetration.

However, despite these strengths, there are methodological issues that need to be taken into consideration for future work regarding the use of GAM. First, the distal portion of GAM has been applied to cyberbullying with studies that have predominately used correlational designs. To be adequately tested the distal GAM needs longitudinal evidence to show the learning mechanisms that are engaged in predicting cyberbullying behavior. Correlational research is paramount for advancing theory, but longitudinal work is desperately needed to show causal connections between variables as a function of extended cyberbullying practices. Second, at the time this chapter is written, I am unaware of any published study that appropriately tests the proximate GAM processes. The proximate processes detail the how situational input factors predict cyberbullying behavior. One approach would be to randomly assign participants to be provoked (or not) and then measure aggressive responding via cyber-attacks. However, in order for this to be a valid paradigm, this necessitates that the two parties involved in the study (the

provocateur and the participant) have some online relationship or online method of causing harm. Further, since cyberbullying would be the outcome in this hypothetical study, quantifying this behavior would be difficult. Finally, since the participant would be in this study, they may not feel as anonymous.

FUTURE: THE NEXT STEP

The psychological literature that has tested the theoretical predictors of cyberbullying behavior is still relatively new compared to the research on (a) the psychological and behavioral consequences of cyber-victimization, (b) the broader traditional bullying literature, and (c) the descriptive predictors of cyberbullying perpetration. Fortunately, there has been much theoretical growth in our understanding of the variables and psychological processes involved in cyberbullying frequency, as the previous section emphasizes. Much empirical work is still needed to further our understanding of the theoretical predictors of cyberbullying behavior. Although this section is speculative, I will offer some ideas for future work to consider.

First, researchers need to carefully consider what measures to use when assessing cyberbullying frequency. Kowalski et al. (in press) found evidence to suggest that the effect sizes between certain cyberbullying related predictors and cyberbullying behavior were higher when the measures did not incorporate a definition of cyberbullying to participants, for example. These effects are important as Rivers and Noret (2009) caution about interpreting frequency rates of cyberbullying frequency in part due to the sheer variety of cyberbullying measures that exist (see Ybarra, Boyd, Korchmaros & Oppenheim 2012 for a recent review of cyberbullying measures). Related, cyberbullying techniques are constantly waxing and waning that corresponds directly with the types of online media that is available. Therefore, researchers need to continuously be changing and altering their questionnaires to attempt to stay current with tools of cyberbullying others. This also corresponds to measurement of cyberbullying attitudes, perceived anonymity, and other possible theoretical mediating variables.

Second, showing incremental validity between the cyber and traditional types of bullying is important. As previously noted, the correlation between both types of bullying is highly significant (e.g., Barlett & Gentile 2012). Thus, any model that claims to predict cyberbullying needs to empirically show that the strength of the relations between the cyberbullying predictors and behavior remains after taking traditional bullying frequency into account. Indeed, this will directly address the criticism levied by Olweus (2012) by showing that cyberbullying is unique, albeit, related type of bullying behavior. Models that fail to statistically control for traditional bullying or show incremental validity beyond traditional bullying effects are still useful; however, conclusions drawn regarding any effects need to be interpreted with a certain degree of caution.

Third, longitudinal work is desperately needed to further test the postulates of some of these theoretical models as they pertain to cyberbullying frequency. Of the four theories discussed, only the BGCM has received replicated longitudinal support. However, even the longitudinal work of Barlett and colleagues (Barlett et al., in press; Barlett 2015) suffers from employing short time frames between data administration times. If such longitudinal work can be conducted, then at least three waves of data collection need to be utilized in order to appropriately test for mediating mechanisms while adhere to strict definitions of temporal

precedence that is a necessary requirement for mediation (Baron & Kenny 1986). Related, the use of certain models that take advantage of proximate (or short-term) predictions can utilize controlled experimental research. For instance, researchers using the General Strain Theory can randomly assign participants to be provoked online (e.g., a cyber-victimization strain) that should be related to subsequent negative emotions (assessed using a state-based affective measure, for example) and cyber-aggressive behavior. Researchers need to carefully validate and select the provocation and measures; however, such a study would be theoretically important and show causal relations between variables.

APPLIED EXTENSIONS

Understanding how several variables can theoretically predict cyberbullying perpetration is not only important to advancing our understanding of the psychological processes involved in elucidating cyberbullying frequency, but also has applied implications. Indeed, if theory can be tested, re-tested, re-formulated or changed (if necessary), and replicated across various populations while utilizing various measures, then intervention efforts can be developed to, hopefully, reduce cyberbullying perpetration. For instance, if anonymity perceptions are integral at predicting cyberbullying attitudes and behaviors (see Barlett et al., 2014; Barlett & Gentile 2012; Barlett et al., in press; Barlett, 2015), then designing an intervention aimed at informing youth that they are not as anonymous as they think they are online and how tracking IP addresses can help to uncover how a seemingly anonymous mean technological correspondence can be traced back to the original sender, should reduce cyberbullying behavior through the reduction of cyberbullying attitudes.

Currently, there are few published cyberbullying intervention techniques that have shown success. Indeed, Ahlfors (2010) conducted a descriptive study of cyberbullying prevention websites and concluded that the majority of these websites provided information helpful for parents of cyber-victims, which may be problematic considering often parents are unaware of their children's online behaviors. This suggests that more traditional intervention methods may be required (see Snakenborg, Van Acker & Gable 2011 for an interesting review). Kowalski and Agatston (2008; 2009) have outlined an 8-session school-based curriculum for various school-aged youth aimed at reducing cyberbullying behavior. Upon examination of the curriculum for these interventions, it is clear that the purpose of the intervention is to cognitively shift one's beliefs towards reducing positive attitudes towards cyberbullying. For instance, session 3 of the Kowalski and Agatston (2009) intervention has youth identify how to use technology in a positive way, while session 4 has participants state why cyberbullying is unacceptable. This would conform with the Theory of Reasoned Action (Ajzen & Fishbein 1991), the General Aggression Model (Anderson & Bushman 2002), and the BGCM (Barlett & Gentile 2012) by suggesting that if the intervention is successful, the youth (after session 4) should understand and begin to internalize that cyberbullying behavior is unacceptable, which should reduce positive attitudes towards cyberbullying, a key variable in these models. However, more can be done in this regard to incorporate theory into these intervention strategies. For example, Barlett et al. (in press) and Wright (2013) found longitudinal evidence to suggest that anonymity is an important predictor of cyberbullying behavior. Thus, if kids can be taught that they are not as anonymous online as they perceive themselves to be, then that

should also aid in reducing cyberbullying attitudes and could accompany these already existing interventions.

Salmivalli, Karna, and Poskiparta (2011) validated an anti-bullying program, termed KiVa, in Finland (see also Karna, Voeten, Little, Poskiparta, Kaljonen & Salmivalli 2011). They sampled 78 schools including 5,651 fourth to sixth graders and randomly assigned them to a control or KiVa program. The KiVa program is a 9-month intervention that includes presenting participating kids with lectures, videos, group activities, and student exercises. Additionally, self-reported victims and bullies are included in these discussions along with having these students lead certain groups through the KiVa program. Although this program does not focus solely on cyberbullying, the curriculum matches what Olweus (2012) discussed in terms of housing cyberbullying intervention programs within larger bullying interventions. Results showed that, relative to control schools, those schools that engaged in the KiVa program had a reduction in their cyberbullying behavior (36% decrease from pre- to post-test); whereas the control schools had an increase in cyberbullying (14% increase from pre- to post-test). According to Karna et al. (2011), the KiVa program focuses on "...positive change in the behaviors of classmates can reduce the rewards gained by bullies and consequently their motivation to bully in the first place" (pg. 313) while focusing on enhancing empathy and anti-bullying attitudes. Again, more work can be done to add to this program based on the theoretical rationale detailed earlier in this paper.

Additionally, if broader psychological theory can be validly applied to cyberbullying behavior, as suggested in the extension of the General Aggression Model, then already established interventions aimed at reducing aggressive behavior (more generally) or bullying should also reduce cyberbullying behavior. Although speculative, if research has found that empathy is negatively related to cyberbullying behavior (e.g., Ang & Goh 2010) and interventions have already been validated and shown to increase empathy (e.g., Feshbach & Feshbach 1982), then similar interventions should help reduce cyberbullying behavior. Indeed, Karna et al. (2011) already integrated this into their KiVa anti-bullying program. However, other untested psychological variables can be examined. For instance, research has shown that narcissism is positively related to cyberbullying (Ang, Tan & Mansor 2010), which is predicted from GAM (see Kowalski et al., in press for this extension). In a field study, Thomaes, Bushman, De Castro, Cohen, and Denissen (2009) found that having youth engage in positive self-esteem training via self-affirmation techniques can prevent narcissistic youth from engaging in aggressive behaviors after an ego threat. It stands to reason that teaching self-affirmation practices may reduce cyberbullying perpetration; however, this is speculative.

One issue that I believe warrants explicit attention is that researchers, psychologists, educators, parents, and others who are interested in the reducing cyberbullying should heed the data and conclusions from Olweus (2012) who argued that since cyber-victimization frequency tends to be lower than traditional bullying victimization, anti-bullying interventions should not shift to cyberbullying while ignoring traditional bullying frequency. I agree with this statement and urge researchers to incorporate cyberbullying into an already existing anti-bullying campaign. The KiVa anti-bullying program along with the work by Kowalski and Aganton (2008; 2009) adhere to this suggestion, but I think it would be a mistake to only focus on cyberbullying prevention and ignore traditional bullying. However, I do think that these anti-bullying interventions do need to pay attention to the theoretical advances made in the cyberbullying field to inform interventions appropriately. Due to the definitional, measurement, and psychological differences between both cyber and traditional bullying frequency (see

Vanderbossch & Van Cleemput 2008), there may be reason to include cyberbullying effects into an already existing bullying or aggression-reducing intervention program. Science has gone great lengths to show under what conditions such interventions work. For instance, a meta-analysis of aggression-reducing interventions showed that anti-aggression interventions were most successful for high risk youth in an “intense” program delivered by a trained professional (compared to a layperson) using a one-group design (Wilson, Lipsey & Derzon 2003). Additionally, meta-analysis focusing on traditional bullying intervention programs found that youth in the bullying prevention group reported being bullied less, witnessing less bullying, bullied others less, and had higher self-esteem relative to youth in control conditions (Merrell, Gueldner, Ross & Isava 2008). Looking at moderators, another meta-analysis found that intervention programs aimed at reducing bullying were especially successful when the intervention had a long duration, was intense, included school conferences, teacher training, and classroom-rules, and if the entire school participated (Ttofi & Farrington 2011). Researchers interested in drawing on these literatures for cyberbullying reduction should adhere to some of these recommendations.

CONCLUSION

It is an exciting time to investigate the predictors of cyberbullying behavior. The field has entered a phase where enough theory is out there to be applied reliably, but many questions still remain. I believe that if theory can be appropriately validated, then interventions can be created (or refined) to incorporate reducing the correlations between cyberbullying predictors and behaviors.

Chapter 3

MEASURING CYBERBULLYING: TOWARDS AN INTEGRATIVE APPROACH TO ASSESSMENT

Julia Fluck*, PhD

University Koblenz-Landau, Centre for Educational Research (zepf),
Landau, Germany

INTRODUCTION

Cyberbullying is still a rather new phenomenon and therefore it has only been in the focus of researchers for around a decade. It was not the scientific community, but the media, who first brought this phenomenon to the awareness of the public. Newspapers and bloggers wrote about spectacular cases, where victims attempted or even committed suicide after being harassed online. It was only after that, that researchers in different parts of Europe, Canada, Australia, and the United States began to take an interest in this new kind of violence as well. However, as Menesini & Nocentini (2009) put it: "...there has been little focus on the measurement issue of cyberbullying. Indeed in bullying research generally, some scholars have claimed that insufficient concern is paid to psychometric issues in bullying research as well as to the need for more detailed comparison between different methods" (p. 230).

Addressing this criticism, this chapter focuses on aspects of measuring cyberbullying. In the following sections, the most prominent problems in cyberbullying research will be discussed, several possible measurement strategies will be presented and described, and a conclusion will be given with the proposition of an integrative model that combines the advantages of the discussed approaches. The remarks in this chapter all relate to self-assessment, to methods where the bullies and the victims themselves provide information on the bullying. Peer-assessment has also been used in cyberbullying research, advantages and problematic aspects of this approach go beyond the scope of this chapter, for a discussion see Espinoza & Juvonen (2013) or Card (2013).

Methodological Problems in Cyberbullying Research

The most common questions in the earliest studies on cyberbullying were often the same:

- Does cyberbullying exist in our country (e.g., Riebel, Jäger & Fischer 2009)?
- Are the bullies and the victims of cyberbullying the same children and adolescents who are involved in traditional bullying as well (e.g., Raukaskas & Stoltz 2007)?
- How can we describe cyberbullies and cybervictims? Are girls more often involved than boys, because cyberbullying is an indirect form of bullying? Or are boys using the internet as a new tool for an old behavior? At what age do children begin to cyberbully and what is the most “dangerous” age to become a victim? (e.g., Kowalski & Limber 2008)

The first question concerns the prevalence of cyberbullying and is almost impossible to answer without representative random samples, clear definitions of the construct, and cross-culturally validated questionnaires. For example, the first two German studies both came to the conclusion that cyberbullying exists and is a problem in the country. A lot more than that cannot be drawn from the results, at least not on the question of prevalence. Jaeger, Fischer, Riebel, and Fluck (2007) used an online study, which is not representative of the German population of students. Katzer (e.g., 2009) focused on bullying in chat-rooms only, leaving out cyberbullying via text message, email, instant messenger, and social networking sites. Depending on the study one consults, prevalence rates for cyberbullying vary between six and seventy-two percent (Ybarra 2013) – apparently, there must be something wrong with the measurement!

The second question concerns the overlap with real-life or, as it is often called, traditional bullying. Not surprisingly, most studies come to the conclusion that there is a substantial overlap between being a bully online and offline, being a victim online and offline, and between being a victim offline and a bully online. However, the overlap is far from perfect: Riebel et al. (2009) reported a correlation of $\phi = .586$ between being a cyberbully and being a real-life bully, and a correlation of $\phi = .324$ between being a cybervictim and a real-life victim. As these correlations are far from perfect, they tell us not much more than: Cyberbullying has something to do with traditional bullying, it is not a completely distinct phenomenon, but neither is it the same as (or just another sub-type of) traditional bullying. This is, like the findings on prevalence rates of cyberbullying, not exactly a ground-breaking scientific discovery.

The third question concerns the socio-demographic and personality features of bullies and victims. This question is rather interesting and if the results were valid in a psychometric sense, they would surely be of great value for the public, parents, teachers, and students. The only problem is: in order to answer the question about the relationship between cyberbullying and other variables (e.g., age, gender, personality traits, empathy) we have to measure both constructs and correlate them. But how can we measure cyberbullying? The truth is: We do not know.

The three major questions from the early years were actually asked too soon. We should have put them secondly, and started by asking what cyberbullying is (i.e., “How do we define it?”), what behaviors are a part of it, and how we can measure it. In other words: “Cyberbullying research has addressed substantive problems and between-construct issues before within-

construct issues such as definition, structure, and measurement have been resolved” (Craven, Marsh & Parada 2013, p. 68). In his review, Tokunaga (2010) listed the most pressing problems of current cyberbullying research, such as inconsistent definitions, lack of psychometrically sound questionnaires, absence of theory, simplistic correlations, and the lack of longitudinal studies. These points will now be discussed in and it will be evaluated if, to what extent, and how these problems could be solved in the nearer future.

1) Different research teams use different definitions of cyberbullying, which can have severe consequences especially when using single, one-dimensional questions. Imagine the following scenario.

In study A, the researchers define cyberbullying as “bullying via electronic devices,” and therefore use the defining criteria for traditional bullying (imbalance of power, repetition, intent to hurt). In study A, incidents are only labeled as “cyberbullying” when they occur more than three times and with an explicit intention to hurt the victim.

The researchers who carry out study B use a broader definition and consider all acts of “hurting someone online” as cyberbullying.

Both studies investigated prevalence, and the overlap with traditional bullying and empathy. Study A will probably yield a lower prevalence than study B, a greater overlap with traditional bullying, and a lower value for empathy in the bully. Now, readers who only interpret the findings of one study, but not the other, might draw oversimplified conclusions on the nature of cyberbullying.

In order to address this problem, the gold standard solution would be to establish defining criteria that are accepted and used as a basis for cyberbullying assessment by all researchers. This could be done by developing standardized questionnaires, which are then validated in different countries and languages. However, this solution is too utopic, at least for the nearer future. An interim solution might include a minimum standard of describing – in detail – how cyberbullying was defined and how (with what questions, what scaling) it was measured. Also, conclusions about the nature of cyberbullying should not be drawn from single studies. Reviews (e.g., Dooley, Pyżalski & Cross 2009; Tokunaga 2010) and meta-analyses (e.g., Kowalski, Giumetti, Schroeder & Lattanner 2014) can help classify and understand results from studies.

2) Until now, there are no questionnaires that are widely accepted as a standard assessment instrument. Early in cyberbullying research, every researcher interested in the phenomenon developed their own way of assessing it, which leads to a now vast amount of instruments (for an overview see Kowalski et al., 2014) and hundreds of study results that are – strictly speaking – not comparable to each other. Lately, there have been endeavors to develop, validate, and publish standard instruments (for an overview and an evaluation of instruments see Berne et al., 2013), so the future might bring improvements in this area.

3) The most prominent problem in cyberbullying research is the almost complete absence of theory in the early studies. This is not surprising since cyberbullying is still a new phenomenon, which did not exist before the new millennium. When the media started to report on it, researchers took an interest in it as well and started to conduct the first studies in order to find out if the problem existed in their countries and how big a problem it was. Especially due to the multiple disciplines that take an interest in cyberbullying – psychologists, sociologists, media and communication scientists as well as educational scientists ({Smith #365}) – in the

first years no one bothered to try and integrate the phenomenon into existing theories of human behavior.

Lately, there has been a change in this practice, with attempts to understand cyberbullying within the frameworks of general strain theory (Patchin & Hinduja 2011) or the theory of planned behavior (Pabian & Vandebosch 2013).

4) This trend might help to tackle another problem: The fact that most studies only investigate simplistic correlations between cyberbullying on the one hand and some other construct on the other. The experts coming together at the XIII. Workshop Aggression in Berlin (2014) agreed that cyberbullying research needs complex models.

5) The last problem was mentioned by Tokunaga (2010). He explained that the majority of studies are cross-sectional in nature. More longitudinal studies are needed to detect causal dependencies between the correlating constructs.

All of these problems, and the unfortunate situation concerning their solution, makes it most pressing to address within-construct issues. What we need is a universally accepted definition of cyberbullying and methods for reliable and valid measurement. In the remainder of this chapter, the different ways in which cyberbullying can be measured and advantages and disadvantages of this measurement as well as recommendations on future practice will be discussed.

Possible Ways to Measure Cyberbullying

Measuring intergroup phenomena like (cyber)bullying is a difficult endeavor. Asking about the specifics of who did what to whom and with whose help can only be applied to very specific situations. One specific situation, however, does not constitute bullying (which, per definition, requires the aspect of repetition). So in order to assess victim-status, we automatically have to ask about a variety of situations which requires longitudinal designs.

Many researchers ask for the cyberbullies' - as well as the cybervictims' perspective. While a victim's answers might be more truthful and less affected by social desirability, some questions (e.g., about motives) can only be assumed by the victim and probably be better answered by the bully (Tremblay & Edward 2005). It is advisable to always consider both perspectives in order not to overlook the considerable number of bully-victims (e.g., Riebel 2008 reports 32% for a German sample).

While some authors work with qualitative data, like interviews (Ševčíková & Šmahel 2009), most cyberbullying research uses questionnaires, leading to quantitative data. Therefore, cyberbullying might be measured "on the base of a global definition" or with "a multiple-item-scale or description of specific acts" (Menesini, Nocentini & Calussi 2011, p. 267). On the other hand, the answer format can vary from dichotomous (yes-or-no) questions to rating scales with several (usually four to six) options, such as ranging from "never" to "often." Table 1 provides an overview of the four combinations of questions and answer format.

Dichotomous Questions versus Rating Scales

Table 1 shows that while dichotomous questions only allow participants to answer an item with yes or no, rating scales have more options. In current cyberbullying research, we can find

examples of both approaches: Patchin and Hinduja (2011) use a multiple-item-scale that lists several cyberbullying behaviors with a dichotomous answer format, while Smith and colleagues (Smith et al., 2008) use a rating scale for multiple-item-scale of different media, where the participants have to choose between having experienced bullying never, once or twice, 2-3 times a month, about once a week or several times a week within the last two months.

Both approaches have advantages and disadvantages (Underwood & Card 2013): Dichotomous items might add to the impression that the world can be strictly divided into victims and non-victims (the same is true for bullies), with nothing in between. With rating scales, we get continuous variables that allow the view of bullying and victimization as a continuum. Here, someone who suffers from daily bullying that hurts him or her badly is not put in the same category as someone who gets attacked once, reacts sad and hurt at first, but can shrug off the experience after a while.

Table 1. Overview on measuring approaches

	dichotomous question	rating scale
singular global question	Approach A Cyberbullying is defined as [...]. Are you a victim of cyberbullying? ↪ yes ↪ no	Approach B Cyberbullying is defined as [...]. How often have you experienced such behaviors? ↪ never ↪ once or twice ↪ several times per month ↪ daily
multiple- item-scale	Approach C Have you experienced any of the following behaviors? bullying with text messages ↪ yes ↪ no bullying in chatrooms ↪ yes ↪ no exclusion from online games ↪ yes ↪ no	Approach D How often have you experienced the following behaviors? bullying with text messages ↪ never ↪ once or twice ↪ several times per month ↪ daily bullying in chatrooms ↪ never ↪ once or twice ↪ several times per month ↪ daily exclusion from online games [...]

On the other hand, ratings scale usually yield rather skewed distributions. Figure 1 shows an example from a 2013 study on German middle-school student (Fluck 2014).

The variable “cybervictim” does not follow a normal distributions. Most participants report never having experienced cyberbullying, some claim to have experienced cyberbullying a few times, and only 2.7% are victims of cyberbullying in a strict sense of the definition (with experiences once a week or more often). As distributions often look that way with cyberbullying data, one might argue that a rating scale does not make a lot of sense. However, as Underwood and Card (2013) state, data can always be dichotomized during the statistical

analysis. This is better than limiting oneself and participants' choices to only two answering options.

Usually, rating scales use the following rationale: asking for the number of incidents within a certain time frame. Strictly speaking being a victim of cyberbullying "once or twice" does not make any sense, since bullying requires the defining criterion of repetition. However, children and adolescents are often unaware of this. By asking a singular global question, some participants (who only have experienced virtual violence once) might declare themselves as cybervictims, which will distort the data by yielding too high a prevalence rate. Because of this, it is better to give participants more alternatives for answering and then divide the scale afterwards (for an example see Menesini, Nocentini, & Camodeca 2013). Therefore, using rating scales with at least one middle category between being a victim and not being a victim (respectively being or not being a bully) to allow a distinction between light and severe cases.

Figure 1. Answers to the question "During the last year, how often has it happened, that you were harassed, threatened, offended or excluded by internet or cell phone?" in percents.

One Global Questions versus Multiple-Item-Scales

When assessing cyberbullying with a singular, global question, participants must understand what cyberbullying is by being presented with a definition. By thoroughly reading it, the participants get a mental representation of the cyberbullying construct. In the next step of the questionnaire, they can compare this representation with their individual experiences and decide if they are or are not a victim of cyberbullying.

Using dichotomous questions (approach A, table 1), they are forced to choose between being a victim or not being a victim, while with rating scales (approach B, table 1) they also make the decision if the construct "cybervictim" applies to them, but with the difference, that they have to answer how often they have been affected by cyberbullying. In both cases, the global question forces them to make the decision themselves: "(How often) am I a victim of this construct that is being described here?"

Multi-item-scales (Approach C and D, table 1) do not use the global construct but specific behaviors instead. Before constructing the scale, researchers have to know about the range of possible cyberbullying behaviors and formulate them as items for the scale. As the range of possible behaviors is more or less infinite, the researcher has to categorize them. Common categorization systems are taxonomies by type of action (Willard 2007) or by type of medium (Smith et al., 2008), which are discussed in more detail in section 3.1.

In the current cyberbullying research literature, we find examples for both approaches: for singular global questions (e.g., Ybarra & Mitchell 2004) and for multiple-item-scales (e.g., Smith et al., 2008), as well as a combination of both types. For example, Beran and Li (2005) presented a list of cyberbullying behaviors to their participants and then asked a singular global question (are you a victim?).

Interestingly, some studies with multiple-item-scales report the results (prevalence rates) for each specific item, but do not compute a sum-score of the items in order to get a global value as an indicator of cyberbullying experience. This is a bit surprising, since the advantage of a multiple-item-scale is the fact, that it yields a more reliable measure than a singular global question, when the data from several items are aggregated into a new variable (Murphy & Davidshofer 2005).

Several studies showed that the way of measuring by singular global question versus multiple-item-scale can lead to big differences in results. This, of course, becomes evident only when a study uses both types of assessment and compares the results. Vandebosch and van Cleemput (2010) state that the discrepancies they discovered in their data might be explained by participants not considering all the actions listed in the multiple-item-scale as bullying, probably because some of those actions lack the aspects of “intent to hurt” or “repetition.” Menesini and Nocentini (2009) have another explanation for discrepancies found between the global key questions and the other statements of involvement in harassing acts. In two studies conducted by members of their research group (Menesini, Modena & Tani 2009; Menesini, Nocentini & Fonzi 2007), they explained that: “We might speculate that some adolescents hesitate to label themselves as bullies or as victims, while they could claim to have been involved in one or more bullying episodes as actors or victims (p. 231).” This argument can be supported by data from one of our own studies, where we also used two different approaches and compared the resulting data. Approximately 549 middle school students answered a questionnaire that contained the following questions: (a) Are you a victim of cyberbullying? (Approach A) and (b) During the last year, how often has it happened, that you were harassed, threatened, offended or excluded by internet or cell phone? (Approach B). The difference here was not only the usage of a rating scale in the second question, but also the fact that we avoided the word “victim,” which was used in the first question. Afterwards, we recoded the data from question B into three categories: no experience with violence (code = 0), some experience with violence (code = 1), and regular experience with violence (i.e., fitting the definition of “bullying”) (code = 2). If the participants had the same mental representation of bullying and violence as we do, we should expect the following pattern in the data: (a) Those who have experienced violence on a regular basis (category “2” on the second item) should have labeled themselves as victims on the first item, and (b) Those who have not experienced any kind of violence (category “0” on the second item) should not have labeled themselves as victims in the first item. Table 2 shows, that whilst the second hypothesis holds true in 98 percent of cases (only 5 people who have not experienced any violence labeled themselves as victims), the first hypothesis has to be rejected. Out of 45 students who claim to have

experienced violence on a regular (sometimes daily basis), only 53 percent labeled themselves as victims!

Table 2. Comparison of assessment approaches

		answer on item II			
		no violence (0)	Some violence (1)	regular violence (2)	sum
answer on item I	not a victim	271	200	21	492
	victim	5	28	24	57
	sum	276	228	45	549

Obviously, people hesitate to use the term “victim” for themselves, even if the situation indicates they *are* a victim. Inspecting the middle column of table 1, we can also see that from the 228 persons who experienced some violence, a minority of the 28 (12%) labeled themselves as victims. It would be interesting to know which personality traits are responsible for a person to apply the victim label to him or herself. The following recommendation can be drawn from this example: As participants seem to try and avoid the label “victim”, one should probably avoid this word, even when using global singular questions. (In Germany, “you victim” has become a derogatory term among teens, which is used in order to mark someone as not brave or not assertive). When using the term “victim,” researchers should at the least add a second approach of assessing victim status in order to validate the findings.

Or should we avoid singular global questions completely, when the sum score of a multiple item scale is more reliable? Not necessarily. Menesini & Nocentini (2009) discuss the advantages of the approach: “Arguments in favor of a single-item measure are practical reasons related to quicker administration of the measure and lower cost of data processing. From a theoretical perspective, Rossiter (2002) argues that a single-item measure is sufficient if the construct consists of one concrete object that is easily and uniformly imagined [...]”

Some limitations should be taken into account when using multiple-item scales. First, not all possible bullying acts are necessarily included in that list. This problem is related to the theoretical definition of the phenomenon. Second, not all items are necessarily of equal severity. While some of them may occur more regularly without being perceived as bullying, others may have very long-lasting effects even though they occur only occasionally (p. 231).”

While the arguments of economy might be true, there might be some doubt that cyberbullying is a construct that “consists of one concrete object that is easily and uniformly imagined.” Therefore, in spite of the disadvantages inherent to multiple-item-scales, it might still be recommended as the best way to measure cyberbullying, ideally combined with a rating scale as answer format. However, the question remains which multiple-item-scale should be used? In the following section, we will present and discuss some existing scales.

Multiple-Item-Scales in Current Cyberbullying Research

The construction of multiple-item-scales is not trivial. It is impossible to list all possible acts of cyberbullying behavior. Therefore, the vast amount of possible incidents must be

classified into types of cyberbullying, resulting in a taxonomy that describes clusters of behavior.

This has been done for traditional bullying as well, where behaviors are distinguished into physical, verbal or relational bullying (or sometimes between direct and indirect forms) (Smith & Brain 2000). Physical bullying does not describe a specific act, but is a generic term for all kinds of behavior that include an attack on the body (or the belongings) of a person, such as kicking, punching, hitting, pushing. The classification into physical, verbal, and relational bullying classifies behavior by the type of action the bully uses. Willard (2007) has also proposed a classification by type of action, when it comes to cyberbullying (see below). But beside the very broadly used classification by type of media (Smith et al., 2008), there are many other types of classification that can be found in cyberbullying research (Nocentini et al., 2010). Spears, Slee, Owens, and Johnson (2009) distinguished between overt and covert types of cyberbullying, Vandebosch and van Cleemput (2010) conceptualized cyberbullying as a form of traditional bullying in a new context, and the Berlin Cyberbullying-Cybervictimisation Questionnaire (Schultze-Krumbholz & Scheithauer 2009) distinguishes between relational and technically sophisticated cyberbullying.

In the following section, two approaches (the taxonomy of actions and the taxonomy of media) are described, which often build the basis for multiple-item-scales, and their advantages are also discussed. Later in this chapter, the criteria for a good taxonomy and the question where the clusters should come from is further explained. In the last section of this chapter, we present the taxonomy of reasons and discuss its value in cyberbullying research.

The Taxonomy of Actions versus the Taxonomy of Media

In 2006, Nancy Willard published the first book on cyberbullying. In this volume, she describes what cyberbullying can look like and lists eight possible forms of “online social cruelty.” She uses this term, because not all of the forms make sense in the context of bullying, since they lack aspects of repetition and / or imbalance of power (e.g., flaming = “a heated, short-lived argument” [p. 1]). The forms which can be applied to cyberbullying are:

Harassment (“repeated, ongoing sending of offensive messages;” Willard, 2006 p. 2) can also contain threats toward the victim and is a direct form of contact, where the perpetrator sends a message directly to the victim. That way, it is somehow similar to direct verbal bullying in real life, where someone is being called names, threatened or ridiculed. It is private, because when the harassment happens in a public forum, it becomes denigration.

Denigration is “speech about a target that is harmful, untrue and/or cruel” (Willard 2006 p. 3). Although the victim might be present (in a chatroom or other online environment) or read a denigrating text on a website at the same time as others, the recipient of a denigrating message is not (in contrast to harassment) the victim, but other people. The aim of denigration is to ridicule the victim and to destroy his or her reputation, so it is always a public act. It can be considered a parallel to relational bullying in real life, so it is an indirect form of violence. Denigration can mean spreading rumors or personal information about a victim (text based) but also the unwanted sharing of intimate or manipulated pictures or videos.

“Impersonation occurs when the cyberbully gains the ability to impersonate the target and post material that reflects badly on the target or interferes with the target’s friendships” (Willard 2006 p. 3). Impersonation can be considered a more severe form of denigration. It is also indirect, public, text, or picture/video based and aims to destroy the victim’s reputation. The difference is that the messages seem to come from the victims themselves, which gives the rumor or false information more credibility.

Outing & Trickery: “Outing is publicly posting, sending, or forwarding personal communications or images, especially communications or images that contain intimate personal information or are potentially embarrassing. A common form of outing is when a cyberbully receives an email message from a target that contains intimate personal information and then forwards the message to others” (Willard 2006 p. 4). Trickery is a special type of outing where “an innocent target can be tricked into thinking that a communication or sending of images is private” (p. 4), when in fact, it is immediately presented to a larger audience. It shares the features of denigration and impersonation, with one important distinction: The information is not a rumor, lie or fake picture, but it is most often real and therefore even more embarrassing for the victim.

Exclusion is analogous to exclusion in real life. The internet and new media in general offer many ways to interact not only in pairs of two, but in larger groups. Examples are online games (where multiple players form alliances), chatrooms with text and/or video chats, forums, Facebook groups, and many others. Not including a classmate in a group he or she desires to join is a form of relational aggression. It is an indirect form of bullying and it is always public, because there is always at least one third person who knows about the exclusion.

When using the taxonomy of actions in a multiple-item-questionnaire, I propose combining the four actions with one more dimension, texts versus pictures/videos. Table 3 shows that some of the actions can take more than one form and there is a major difference for a victim between a Facebook post, “Kevin wears pink underwear on his fat ass,” and the posting of a picture that proves this.

Table 3. The taxonomy of actions and the properties of its categories

	direct	indirect	private	public	text	picture
Harassment	x	-	x		x	x
Denigration Impersonation	-	x	-	x	x	x
Outing / Trickery	-	x	-	x	x	x
Exclusion	-	x	-	x	-	-

The taxonomy of media, as proposed by Smith and colleagues (2008) is easy to understand without any explanation. Smith et al. list the following six forms of communications and use them as categories for cyberbullying incidents: phone calls, text messages, chats, instant messengers, email, and websites. Both approaches have advantages and disadvantages. The taxonomy of media can be used to identify the most dangerous media, which can help teachers, counselors and parents decide where they must pay specific attention to. On the other hand, the media are not only merging (e.g., Facebook combines the features of websites, chats, and bulletin boards; smartphones include cameras and email-clients), but new types of communication arise every year, which are not always easy to integrate in the existing

taxonomy. The taxonomy of actions is not so prone to merging and arising of new technologies and covers many different forms of cyberbullying, but it lacks empirical examinations on the dimensional structure of the categories. As mentioned above, questionnaires should distinguish between text-based and picture/video-based bullying, which adds an important aspect to both approaches.

Probably because both approaches have their advantages, both can be found in current studies: Some use action scales (Ang & Goh 2010; Erdur-Baker 2010) and others use media scales (Beran & Li 2005; Ortega, Calmaestra & Mora Merchán, 2008; Slonje & Smith 2008). The action scales are not necessarily based on Willard's (2006) taxonomy. For example, Katzer, Fetchenhauer, and Belschak (2009) used their own list of actions, specified for chat room bullying) and the media scales do not always include the six media Smith and colleagues (2008) used in the original taxonomy. Furthermore, Slonje and Smith (2008) use four types of medium instead of the original six, due to the rather low incidence of the other categories. Similarly, Ortega et al. (2008) only differentiate between internet and phone bullying in their study.

Properties of Good Scales

Which taxonomy of cyberbullying should researchers use? A classification by type of action, a classification by type of medium, or a combination of both? Or should they develop one of their own? In order to compare results, it is often better to use existing assessment practices than to reinvent the wheel with every single study. The approaches proposed by Willard (2006) and by Smith and colleagues (2008) are useful and valid, and I suggest only a few variations when using them in a study. But until now, both taxonomies are only lists of items, many standardized and validated questionnaires do not exist at this point in time. It is hence understandable, when researchers prefer to construct their own multiple-item-scales. But when they do, they should be aware of two major problems associated with scale construction, which will be discussed in the following sections.

Basing the Items on a Theory?

When using multiple-item scales, researchers often do not have a specific theory behind the lists they present to their subjects. The taxonomy of media is a list of the communication tools that were broadly used by internet users at the time of the scale's construction. The taxonomy of actions is based on a practitioner's experience of what virtual attacks included around the year of 2006 (Willard 2006). Both taxonomies are constructed inductively by listing real-life experiences and subsuming them under headlines.

Another approach – generally more common in the social sciences – is to develop the items of the scale deductively, based on a scientific theory. Since cyberbullying is such a new phenomenon, hardly any theories exist. In order to base their questionnaire on a theoretical framework, Vandebosch and van Cleemput (2010) made use of the relationship between cyberbullying and traditional bullying (see table 4), and constructed their items based on the types of cyberbullying they defined as analogous to real-life bullying.

Table 4. Types of cyberbullying (Vandebosch & van Cleemput 2010)

traditional bullying	cyberbullying
direct bullying	direct bullying
physical (e.g., hitting)	
property (e.g., damaging someone's belongings)	property (e.g., purposely sending a virus-infected file)
verbal (e.g., calling someone names)	verbal (e.g., using the internet or mobile phone to insult or threaten)
non-verbal (e.g., making obscene gestures)	non-verbal (e.g., sending threatening or obscene pictures or illustrations)
social (e.g., excluding someone from a group)	social (e.g., excluding someone from an online group)
indirect bullying (e.g., spreading rumours)	indirect bullying
	"outing" of email entrusted information
	masquerading, e.g., deceiving someone by pretending to be someone else
	spreading gossip by mobile phone, email or chat
	taking part in voting on a defamatory polling website

Example items included "Sending excessively large or numerous emails to someone so as to overload their system" or "Breaking into someone else's email or IM program and sending messages in their name." While basing items on a theoretical framework is certainly a good approach, the step from operationalizing the "types of bullying" into specific items is still not trivial. The scale by Vandebosch and van Cleemput (2010), for example, is a mixture of very specific and rather non-specific behaviors and does not cover every possible act of cyberbullying. So, even though it is ideal to have a theory behind a scale, the usability of the scale in practice is also an important point to look after.

What Makes a Good Taxonomy?

A good taxonomy should fulfill two requirements (Jäger 1995). It is supposed to be as disjunctive and exhaustive as possible. Disjunction means that each element can be placed in only one category. An example for a disjunctive taxonomy is categorizing your family tree into members who still live and those who have already died. Great-aunt Hildegard cannot be alive and dead at the same time (always assuming she is not a ghost). In contrast, classifying the weather into just two categories (sunshine versus rain) does not make a disjunctive taxonomy, because it might be the case that it rains and the sun shines. Exhaustion means that there is a category for each element. In practice, this often does not work, and there has to be a last category named "other" for the few cases that fit neither category. Online dating websites ask their clients to give a marital status and let them choose between single, separated, divorced, and widowed. This taxonomy is not exhaustive, because married people do not have a correct option to choose. (In an ideal world, married people would probably not register on a dating platform and this is why the provider doesn't include this category). This taxonomy is, by the way, not disjunctive either, because a person could be widowed and divorced, for instance if they were married twice. An example for an exhaustive (and disjunctive!) taxonomy are the

various blood types. You can either be type A, B, AB or O. To every person, one (and only one) of those four blood groups can be assigned.

Applying this standard to the classification of cyberbullying, multiple-item-lists should at least be exhaustive. Every case of cyberbullying someone experiences should fall under some category in the list. If this is not the case, then some cybervictims, for whose experience there is no category, remain undetected. This does not only affect prevalence rates but other analyses, too. A lack of disjunction is not so serious, as long as specific, singular incidents are not asked about. As cyberbullying is - per definition – happening repeatedly, in many cases, victims experience more than one form of online aggression. Therefore, questionnaires will allow for participants to tick more than one item. When classifying single incidents, however, it is useful when the taxonomy is disjunctive, so the questionnaire yields a clear picture of what happened.

Smith et al.'s (2008) taxonomy of media might not always be disjunctive (e.g., when a private chat message gets copied by the bully and spread via email), but when all currently used forms of communication are listed, it is bound to be exhaustive. Willard's (2006) taxonomy of actions has been proven to be disjunctive as well as exhaustive for singular case descriptions (Riebel & Jäger 2009).

The Taxonomy of Reasons

In addition to the already discussed taxonomies of action and media, another alternative needs to be discussed - the categorization by type of reason (Fluck 2014). The question *why* children and adolescents engage in aggressive behavior is just as important as the exact kind of behavior and what media they use. Of course, this is not a taxonomy that can replace other multiple-item-scales, but should be used to complement them. For researchers, it is interesting to study the motives behind aggressive behavior and how they correlate with other constructs. For practitioners (e.g., school psychologists who carry out a questionnaire study in their school) it is important to know *why* (cyber)bullying happens, because the underlying motives have immediate consequences on the intervention that is needed. For example, when a study shows that the most common motive for bullying is boredom and the least common motive is xenophobia, then it does not make sense to use intercultural training as an intervention.

Literature has recognized a lot of motives for cyberbullying, including striving for resources and material gains, anger, jealousy, boredom, entertainment, dominance, self-worth defense, power, acting out aggressive phantasies online, retaliating, and gaining attention (Walker, Craven & Tokunaga 2013). The taxonomy of reasons tries to order those motives along the “roots of evil,” (Baumeister 2001; Pinker 2011), such as instrumental violence, the need to feel powerful, revenge, ideology, and sadism. Those categories were used by Baumeister (2001) to classify severe aggressive acts of adults, like war crimes, homicide, rape, and serial killing. Still, literature on bullying and cyberbullying suggests that the categories could be applied to life at school as well:

- Instrumental aggression (using violent means in order to achieve an aim that could not be achieved with peaceful methods) can happen in the context of blackmailing (Olweus 1993).
- The need to feel powerful is a universal human motive (McClelland 1987). Aggression is sometimes used to secure or enhance one's rank within the group. Being popular

within the peer group is linked to self-worth and a very important motive for adolescents (Patchin 2006).

- Revenge is discussed in the context of cyberbullying, because computers and the new media can be used to retaliate against an opponent who is stronger in real life, but is just as vulnerable as everybody else in cyberspace (König, Gollwitzer, & Steffgen 2010).
- Ideology can be the motivator for discrimination and bullying of minorities. Although it is usually more the psychological variables that distinguish victims from non-victims, superficial attributes can at least be used as justifications for aggressive behavior (Siann, Callaghan, Glissov, Lockhart & Rawson 1994).
- A form of sadism is the joy of hurting others for fun or out of boredom. Boredom has been identified as one of the main reasons why girls bully their classmates (Owens, Shute & Slee 2000).

Fluck (2014) conducted a study with middle-school students, and the results show that for adolescents in a school setting, all these categories of motives play a role, but that the taxonomy is not exhaustive. Qualitative data analyses show, that in students' everyday lives the following motives for aggression also play a role:

- Relationships: Especially for girls, popularity is dependent on how many friends a person has (Coyne, Archer & Eslea 2006). Conflicts arise when girls fight about who is whose best friend, when students help defend their weaker friends or when issues of jealousy or rejection arise in romantic relationships among young people.
- Group pressure: Bullying (and cyberbullying) is not a dyadic process between bully and victim, but a complex system that includes active and passive supporters of the bully as well as neutral bystanders (Olweus 2003). When a child or a teen is being bullied by a whole group, only a few might have a real motive for hating the victim, and others can go along with the bullying because of group pressure.
- Coping: Bullying is usually seen as a condition that leads to frustration. But aggressive behavior can also *arise* from frustration (Patchin & Hinduja 2011), when the perpetrator does not have constructive ways of coping with negative emotions.

A taxonomy by type of reasons can be useful in order to understand the underlying motives of aggressive behavior among students. Since the categories give no information beyond the motive, it should be combined with other multiple-item-scales instead of being used as standalone. In the following section, the combination of different taxonomies and the advantages of these combinations are described.

AN INTEGRATIVE ASSESSMENT APPROACH

How does the ideal cyberbullying questionnaire look like? In this last section, an exemplary solution to questionnaire construction is presented. Since ideally, more than one multiple-item-scale should be used, a three-dimensional model is suggested as a future direction for

questionnaire construction. The section concludes with a call for questionnaires to include open questions for qualitative data analysis.

The Cube Model of Cyberbullying Assessment

It has become evident from the discussion above, that multiple-item scales should be preferred over singular global questions and that rating scales are in most cases better than a dichotomous answer format. Since the different classification approaches (type of action versus type of medium) all have their advantages and problems, we suggest not to use either one or the other, but to combine them into a multidimensional assessment approach.

Questionnaires should include a scale for type of action as well as one for type of medium, in order to combine the advantages of both approaches. A third scale could ask for the reasons behind an attack. This approach cannot only be used for the assessment of prevalence (by asking “how frequently did you do this / did this happen to you”), but also for correlational studies. We can ask students for what they did (action), how they did it (medium), and why (reason). With this approach we can look deeper into the motivational structure behind cyberbullying and we can find out if the choice of actions and of media depend on the perpetrator’s motive. Figure 2 depicts a cube model of cyberbullying classification with the combination of action, medium, and reason.

Psychometrically, the advantage of a multiple item scale over a singular global question is the fact, that the items can be added up into a sum score (or a mean). This increases reliability and, as a consequence, validity of the test. Building a sum score, however, is of course not possible, when the items come from three different dimensions. A sum score over type of reason does not make a lot of sense, but a sum score could be computed over the type of action and the type of media items.

The cube model cannot only be used as a rationale for test construction, but also as a classification system for single events of cyberbullying. This can help teachers and other educational professionals to classify, order, and document cyberbullying cases. Also, practitioners can develop intervention strategies that apply to the certain types of cyberbullying. After having classified the incident, they can choose the corresponding strategy from the repertoire and act more quickly. Imagine the following scenario: Oliver complains to his teacher about getting hateful texts from Cindy ever since she got hold of his new phone number. Cindy sends him at least twenty messages a day, containing offenses and threats. When the teacher asks what Cindy’s problem might be, Oliver confesses that they used to be friends and Cindy has never forgiven him for ending the friendship. The teacher can easily classify this episode as harassment via text and out of revenge. As harassment is a problem between victim and perpetrator only, the teacher needs to address the problem only with Cindy and Oliver and not with the whole class. The revenge issue tells the teacher to speak to Cindy about forgiveness. As the problem is only based on text messages, the teacher can suggest Oliver gets a new number, among other suggestions.

Figure 2. The cube model of cyberbullying assessment. It combines scales for media (phone, mail, instant messenger, chat, web, text), actions (harassment, denigration and impersonation, outing and trickery, exclusion) and reasons (sadism, ideology, instrumentality, power, revenge, relationships, coping, group pressure). Single acts of cyberbullying can be categorized along the three dimensions. The little cube coloured in grey would be used for an example of sadistic harassment by text message. Abbreviations: SAD = sadism, IDEO = ideology, INSTR = instrumental, POW = power, REV = revenge, REL = relationship, COP = coping, GRP = group processes, HAR = harassment, DEN = denigration, OUT = outing and trickery, EXC = exclusion.

A Plea Mixed Methods

Quantitative data are easy to handle and allow us to get a clear picture of cyberbullying prevalence rates, on its distribution over age, gender, school type, and other variables as well as on the correlation with other constructs. However, the world of new media is changing fast and a questionnaire that includes all common forms of online communication today might be missing out on the latest technology tomorrow. As researchers, we have to stay up to date with what teenagers do, when they go online, how they do it, and with which tools. By including open-ended questions in questionnaires, we can give participants a platform to share their everyday world with us. It helps us stay in touch with the most recent developments and can show us aspects we might not have thought of. Ideally, researchers should use a mixture of both methods, thus combining the advantages of both approaches (Mishna & van Wert 2013). For an example of how the combination of qualitative and quantitative methods was used to investigate motives see Fluck (2014). Also, depending on the research question, a questionnaire is not always the gold standard, especially when it comes to investigating new and fast-

changing phenomena. Interviews or focus groups can give insights where standardized questionnaires cannot.

CONCLUSION

The measurement of cyberbullying is a complex task that leaves the researcher with many possible approaches. After reviewing the literature, the following recommendations can be drawn for the assessment of the construct: The usage of rating scales, which can later be dichotomized should be preferred over the usage of dichotomous items. Multiple-item-scales might prove more reliable and valid than singular global questions. The term “victim” should be avoided when formulating item text. When choosing from existing multiple-item-scales, it is best to use a categorization by type of action combined with one by type of medium while also taking into the account the difference between text-based and picture/video-based bullying. When constructing new scales (inductively or deductively), it is important to investigate if the categories are exhaustive (and disjunctive when for the classification of singular events). Questionnaires should contain items for the bullies’ as well as for the victims’ perspectives in order not to overlook bully-victims’ perspectives. Additional, open-ended questions can yield useful answers for qualitative data analysis, especially when items have been constructed based on theory.

Chapter 4

ADOLESCENTS' PERCEPTIONS OF SUFFERED AND COMMITTED CYBER-AGGRESSIVE BEHAVIOR

***Isabel Cuadrado-Gordillo*, PhD
and Inmaculada Fernández-Antelo***

University of Extremadura, Faculty of Education, Badajoz, Spain

INTRODUCTION

The mode in which people communicate and socialization patterns among adolescents have changed during the last decades. These modes are in constant evolution as a result of the development and proliferation of electronic communication devices. Technological growth and easy access to Internet enables the creation of new cyber scenarios that foster novel forms of communication and interpersonal relationships. These technological advances allow people to exchange information in easier, more entertaining, and faster ways. Internet and smartphones have become an essential part of daily life and social interaction for today's youth. Adolescents spend more time online than ever before. However, despite the prevalent use of Information Communication Technologies (ICTs) in the lives of adolescents, we are only beginning to understand how these tools are influencing adolescents' communication skills and their social relationships. Internet provides innumerable possibilities for growth among youth, including benefits, such as social support, overcoming shyness, identity exploration, and the development of strategies for learning, and improvements in interpersonal and critical thinking skills, as well as educational benefits generated from expansive access to knowledge, academic support, and worldwide cross-cultural interactions. Although most interactions are considered positive or neutral, at times, conflict and violence impose themselves upon balance and harmony.

CYBERBULLYING: A COMPLEX MULTIDIMENSIONAL AND EMERGENT CONSTRUCT

Aggression that occurs using ICTs have generally been grouped under the term cyberbullying, an emergent concept that researchers are still debating (Pieschl, Porsch, Kahl & Klockenbusch 2013). Some authors consider cyberbullying to be an indirect form of bullying that needs technological resources to be carried out (Law, Shapka, Hymel, Olson & Waterhouse 2012). Thus, the two phenomena, bullying and cyberbullying, share the same defining criteria: intent to hurt, imbalance of power, and repetition (Pieschl et al., 2013). Other authors argue that they are two different concepts, each with its own characteristics that define and differentiate it (Casas, Del Rey & Ortega 2013). Although cyberbullying is defined as an aggressive, intentional, and repeated act or behavior carried out using ICTs against a victim who cannot easily defend him or herself, cyberbullying has its own identifying characteristics. These include anonymity of the bully, the ability of the act to reach a larger potential audience (publicity), the difficulty of disconnecting oneself from the cyber environment, lower levels of supervision, decreased time and space limits, decreased level of direct feedback between the bully and the victim, and certain emotional considerations stemming from the absence of the direct face-to-face contact which is present in many types of traditional bullying.

In relation to the aggressor's intent to hurt – to inflict pain, fear, or harm on the victim, in the cyber context, the detection and application of this criterion involves certain difficulties related to the nature of communication in this context. In a virtual environment communication it is difficult to understand a person's emotions or really understand the consequences of one adolescent's behavior (Naruskov, Luik, Nocentini, & Menesini 2012). On the other hand, Shariff (2015) states that cyberbullying can also be unintentional for digital natives, or children growing up immersed in digital media, because they often fail to appreciate the difference between jokes and intentional harm.

Another criterion identifying cyberbullying is also from the classical bullying phenomenon – the repetition of the aggression. Nevertheless, in the case of cyberbullying, repetition does not necessarily imply a succession of violent acts from the same attacker. Slonje, Smith, and Frisén (2013) proposed that the victim can experience a single aggression on numerous occasions due to the permanent and public nature of virtual communication. Even though private and compromising material owned by the victim may be sent only once, it may be seen and then broadcast by several people, causing the victim more pain and lasting a longer time (Dooley, Pyzalski, & Cross 2009). If something is posted on the internet by the perpetrator only once, it can be seen by multiple people and it becomes extremely difficult to control or remove it because the information may have been downloaded, saved, and/or forwarded to a large audience. Moreover, Langos (2012) relates repetition to intent in cases of direct cyberbullying, understanding that when abuse occurs again and again it is clearly shown not to be an isolated or inadvertent act, but an intentional one. Without the presence of this factor, conduct may arguable be described as cyberjoking or playful cyberteasing in the cyber space. In sum, according to Nocentini et al. (2010), repetition is firmly established as being a key criterion in cyberbullying.

A third criterion attributed to the definition of cyberbullying is the existence of an imbalance of power between the aggressor and victim. According to Grigg (2010), in the cyber context the imbalance is materialized in situations where victims cannot easily defend

themselves. This asymmetry of power between the aggressor and the victim does not refer to the physical, emotional, or psychological superiority of the aggressor, but to an asymmetry in the ICT domain (Slonje et al., 2013). Knowledge of and competence in using ICT tools provides access to victims' private virtual spaces in order to disseminate information or materials stored there, steal their identity, and create obstacles against identifying the aggressor (Casas et al., 2013). Grigg (2010) also alludes to a social imbalance caused by the difference in status in favor of the aggressor, which is augmented by the support of the group or social network in which the aggressor may be very popular. Other authors interpret the imbalance of power as a symbiotic relationship with other criteria, such as the intent to hurt (Nocentini et al., 2010) or the anonymous or public nature of the aggressor (Dooley et al., 2009; Slonje & Smith 2008). Naruskov et al. (2012) indicated that intentionality is important but it cannot be viewed independently from the imbalance of power because the effect on the victim and his/her perception of the acts can also be more relevant than the intentions behind the aggressor's behavior. Similarly, the anonymous and public nature of the attack and the continuous availability of the victim may create an imbalance in power relations (Moore, Nakano, Enomoto, & Suda 2012).

A fourth criterion distinguishing cyberbullying is the anonymity which protects the aggressor. The possibilities of concealment offered by technological and cyber media without the need for any very advanced technical knowledge can significantly influence the way people resolve their conflicts. Specifically, Kowalski, Limber, and Agatston (2008) argue that anonymity may encourage some people to act in a way that they never would in real life. This effect might help to disinhibit cyberbullies, making it easier to say, write, or send things they normally would not in physical contexts. Anonymity protects perpetrators and presents them with an opportunity to act covertly and make it more difficult for the victim to tolerate. Nevertheless, while anonymity is considered a specific criterion of cyberbullying, there are studies that show that most of the victims recognize their cyberaggressors and identify them as peers belonging to their school or to their closest social environment (e.g., Mishna, Saini & Solomon 2009; Slonje et al., 2013).

The final defining criterion of cyberbullying corresponds to the open and uncontrolled dissemination of the aggressive behavior, i.e., advertising it. Despite this being one of the most widely occurring criteria in acts of cyberbullying (Patchin & Hinduja 2010), some researchers caution that it should not be considered an essential characteristic defining and delimiting an act of cyberbullying, although they do recognize its relevance in reflecting the seriousness of the aggressive act (Nocentini et al., 2010).

DISCREPANCIES BETWEEN RESEARCHERS' AND ADOLESCENTS' CONCERNING THE CONCEPTUALIZATION OF CYBERBULLYING

The study of the dimensions and characteristics specific to cyberbullying allows one to redefine this construct so as to design tighter and more effective prevention and intervention programs. The numerous controversies and contradictions that still exist about the boundary defining this phenomenon show the need to undertake further research focused on the perception that parents, educators, and adolescents have of cyberbullying. If the perception of those involved in this type of cyberaggression is very different from how researchers

conceptualize it, this will not only mean that we are faced with the description of quite different realities, but also that the effectiveness of prevention and intervention programs will be undermined.

Previous studies have shown that the interpretations that researchers and adolescents make of both the bullying phenomenon and the ways in which it is manifested are very different, and that sometimes adolescents define some behaviors as bullying that researchers would classify as occasional aggressions and that adolescents might consider behaviors as social interaction behaviors while researchers would classify these behaviors as bullying (Cuadrado 2011). Our review of the scientific literature on the perception that adolescents have of cyberbullying found only a sparse occurrence of publications, and the existing studies present results that can only be considered exploratory. Some researchers warn of the difficulty that adolescents (Mishna et al., 2009) and adults (Grigg 2010) have in differentiating cyberaggression from an episode of cyberbullying. In a study of 38 pupils of US grades 5-8, Mishna et al. (2009) conclude that the type of involvement in cases of cyberbullying significantly influence the defining criteria considered for this construct. They also note that, as the age of the pupil increases, the anonymity criterion becomes more relative and loses importance. Similarly, Dredge, Gleeson, and de la Piedad (2014), in considering the role of victim, argue that experiences of victimization shape the perceptions that adolescents have of cyberbullying.

Other studies have addressed the establishment of first- and second-order criteria by analyzing whether the combination and interaction of some of them could be key indicators to differentiate cyberbullying from cyberaggression. Thus, Bass, de Jong, and Drossaert (2013) focus on the intent and repetition criteria, analyzing their use by 287 children aged 11-12. Their results showed that the perception of these criteria in the cyber context is ambiguous and arbitrary, and it is therefore impossible to determine whether the relationship between the two is the criterion most often used to define cyberbullying. Nevertheless, Menesini et al. (2012) find that European adolescents tend to believe that if the behaviors is repeated then it cannot be classified as unintentional.

The greater relevance of certain criteria over others is also studied by Nocentini et al. (2010), with samples from different European countries. Their results show that there are two criteria that adolescents attach particular importance to in differentiating a cyberaggression act from an episode of cyberbullying: intent and imbalance. Dredge et al. (2014), however, find that there are few young Australians who take the intent to hurt and imbalance of power as essential components in the definition of cyberbullying. Instead, they emphasize the importance of other possible components, such as the impact that the aggression has on the victim. Nocentini et al. (2010) and Menesini et al. (2012) indicate that, although adolescents consider anonymity in determining the impact that cyberaggression has on the victim, they do not see it as a defining characteristic of cyberbullying. These authors also suggest that adolescents do not consider 'advertising' the abuse to be a criterion classifying a cyberaggressive act as cyberbullying. Sticca and Perren (2013), however, indicate that Swiss adolescents attach particular importance to the public dimension of cyberaggression, and consider it to be a defining characteristic of cyberbullying that determines the severity of the harm caused. In the same line as the previous studies, Naruskov et al. (2012) analyzed the perceptions that 20 Estonian secondary education pupils aged 9-15 have about cyberbullying. They also investigate the application of defining criteria to the different forms in which this phenomenon is manifested. Their results showed that adolescents consider five criteria to define cyberbullying: intent to hurt, imbalance of power, repeated aggressive behavior, anonymity, and advertising.

These authors warn, however, that adolescents do not simultaneously apply these criteria to the variations of cyberbullying that researchers have defined. Only visual abuse (characterized mostly by the dissemination of photos and videoclips) and impersonation are, in the opinion of the pupils, what best represent the construct of cyberbullying, as opposed to exclusion and written or spoken aggression.

Another interesting contribution to the study of perceptions about cyberbullying is that of Vandebosch and Van Cleemput (2008). In addition to analyzing the importance that 279 Belgian adolescents aged 10 to 19 attributed to each of the cyberbullying identifying criteria, they established a differentiation of perceptions according to the role played either as a cyberaggressor or as a cybervictim. Their results indicate that, regardless of their type of involvement in cases of cyberbullying, adolescents considered the repetition criterion to be a key feature with which to distinguish this phenomenon from cyberaggression. In contrast, they downplayed intent to hurt, understanding that sometimes the behavior does not intend to cause harm. In these cases, intent is subject to personal interpretations and sensitivities. Considering the role played, Vandebosch and Van Cleemput (2008) noted that the intent criterion is very clearly present in aggressors' descriptions of cyberbullying, whereas for the victims whether or not they attribute intent to cyberbullying depends on the type of behavior they have suffered and their relationship with the aggressor. If they know the aggressor's identity, and it is a friend, the behavior will be interpreted as fun. However, if the identity is unknown or it is a person whom they find unpleasant or whom they receive threats from prior, the intent to hurt is attributed immediately. Another perceptual difference recorded that depended on the role played referred to the relationship that aggressors and victims established between imbalances of power and anonymity. The aggressors believed that they operated anonymously or camouflaged against people they know in the real world and whom they perceive to be weaker. The victims do not know their aggressors, and this increases their sense of helplessness and insecurity.

HOW THE EXPERIENCES OF AGGRESSION AND VICTIMIZATION AFFECT ADOLESCENTS' PERCEPTIONS

Although previous research studies have addressed the perceptions adolescents have about cyberbullying, their results are very different. The explanation of the discrepancies in the results may be the use of different questionnaires and the small size of some of the samples. Moreover, the contributions of previous studies on this topic have focused primarily on the perception of cyberbullying construct without considering the interpretation that adolescents make of the different modes in which this phenomenon can manifest. This present work provides an instrument that, first, permits identification of the adolescents who play the roles of cyberaggressor and cybervictim. And second, it allows one to determine the criteria that adolescents use to differentiate a cyberaggression episode from a cyberbullying episode, and to identify what types of cyber abuse they consider to be cyberbullying. In this way, one has access to both the adolescents' perceptions of the phenomenon of cyberbullying and its manifestations, and to the specific perceptions presented by those who are or have been cybervictims or cyberaggressors. The objectives pursued in this study were: (a) to determine the perceptions adolescents have about cyberbullying and cyber abuse; and (b) to analyse the influence of

experiences of cybervictimization and cyberaggression on the perception of cyberbullying and its various forms.

METHOD

Participants

In the present work, we try to answer these questions by presenting the results of research carried out in Extremadura (Spain), involving 1,753 adolescents (50.9% male and 49.1% female) with ages between 12 and 16 years ($M = 13.9$, $SD = 1.2$). With respect to the demographic and socioeconomic variables of the sample, it should be mentioned that the geographical area from which the participants were drawn has a very small number of immigrant families or families with racial and cultural characteristics significantly different from those of the autochthonous population. For this reason, there is only a minimal representation in this sample of secondary school pupils with a different cultural, racial, or ethnic profile. Of the total study sample, only 28 had racial or ethnic profiles different from their peers. Such a small, and barely significant, group does not allow any comparative analysis to be made with the rest of the sample population. Also, in composing the sample, it was decided to exclude pupils with some kind of disability so as to avoid the inclusion of other variables that might have had a marked influence on the overall results. The definition of the strata by geographical zones encompassed both central urban populations whose families are of a relatively higher socio-cultural and economic level, and peri-urban and rural populations whose families are of a relatively lower socioeconomic level. The final sample selection had a balance of the two types of profile, with analogous representations. We opted for overall analyses of the entire participant population, excluding any comparative analyses based on differential socioeconomic profiles. The reason for this decision was that all of these teenagers, including those from socially, culturally, or economically disadvantaged backgrounds, have easy access to Internet technologies. They can use these tools in their schools, in their town libraries, or through their friends, when they do not actually have them in their own home. They all, therefore, have the sufficient means to commit or suffer episodes of cyberbullying. In addition, 98% of the teenagers surveyed stated on the questionnaire that they had a smartphone with Internet access. This datum implies that all of the subjects, regardless of their socioeconomic status, are susceptible to being subjected to or committing cyberbullying attacks.

Measurement

The instrument used for data acquisition was a revised version of the questionnaire used by Cuadrado (2012) for the identification of adolescents' criteria identifying bullying. The modifications made were to replace the concept of bullying by that of cyberbullying, and in incorporating new response options to consider other possible defining criteria such as publicity/privacy, anonymity/familiarity, among others. The final version consisted of 43 questions. The first three allow identification of the aggressors, victims, and witnesses of

cyberbullying. These three questions ask about the variations of cyberbullying the adolescents suffer, commit, or observe. The classification criterion of these variations is “type of behaviour.” Drawing on studies by Huang and Chou (2010), Kowalski, Limber, and Agatston (2012), Rivers and Noret (2010), and Willard (2006), we considered a total of eight categories: insults (including homophobia), threats (including blackmail), spreading false rumors (in order to harm the reputation, damage friendships, or to humiliate), exclusion (from contact lists, social networking, etc.), impersonation (another's identity is used to send or post material of insulting, inappropriate, or embarrassing content in order to damage the reputation or the friendships of the victim), sexting, publication of denigrating images or videoclips, and recording and disseminating physical aggressions. For the study of each of these categories, questions were included relating to the use of different technological resources (i.e., chats, e-mails, forum, smartphones, social networking) through which these abuses were carried out. The adolescents answered these questions indicating how often they committed, suffered, or observed each type of abuse during the past two months. The scale used is composed of four values: never, once or twice, once a week, and several times a week.

The remaining 40 questions that make up the questionnaire are oriented toward the analysis of the perceptions that adolescents have about cyberbullying and the various forms in which it is manifested. Each of these questions contained different, not exclusive, response options in which we introduced references to the repetition of abuse perpetrated, the aggressor's intent to hurt, the imbalance of power between the aggressor and victim, the anonymity behind which those who abuse others hide, the advertising made of the aggression, the revenge the victims resorted to in order to compensate for their pain, the forms of communication and social interactions adolescents employ in the cyber world, and the ways adolescents had fun with technology or cyber media, among others. To respond to each of the situations presented in the questionnaire, we opted to use a numerical scale with which one can easily establish distances or differences among participants. This scale consists of 5 values from 1 to 5 representing the respondent's degree of agreement with the responses to the items of the questionnaire: (1) *strongly agree*, (2) *agree*, (3) *neither agree nor disagree*, (4) *agree a bit*, (5) *disagree*. It was necessary to make an initial factor analysis to reduce the number of variables to consider, reflecting the main factors explaining the variability, with the relative importance of each and the relationships between them. In the second phase, it was necessary to identify the adolescents who defined themselves as aggressor or victim, and perform a new exploratory factor analysis to determine whether their definitions of cyberbullying varied according to their role in the different cyberbullying situations they experience.

RESULTS

Adolescents' Perceptions of Cyberbullying

The approach to the perceptions that adolescents have of this phenomenon requires knowledge of both factors or criteria that shape their definitions of this concept and of what they think are the possible behaviors in which cyberbullying may be manifested. For adolescents, the definition of this construct may be complex. However, the detailed description

of its application was expected to be simpler for them, and would thus facilitate our acquisition of a more global and comprehensive vision of the bases of their perceptions of cyberbullying.

The diversity of the responses required the application of a first exploratory factor analysis to group the responses depending on their interrelationships, and thus delimit more generic criteria. The resulting KMO index of .84 and a significance level in the Bartlett sphericity test of .001, provided the sufficient guarantee of reliability of the results.

The principal component analysis showed that, although in principle up to seven factors were detected as present in the concept adolescents have of cyberbullying, only four explained the variability of the responses and provided a closer approximation to the general perception that more than 86% of the participants has (Table 1).

Table 1. Total Variance Explained by the Components

Component	Initialeigenvalues			Extraction sums of squared loadings		
	Total	% of variance	Cumulative %	Total	% of variance	Cumulative %
1	4.82	38.57	38.57	4.82	38.57	38.57
2	2.65	19.24	57.81	2.65	19.24	57.81
3	2.04	16.73	74.54	2.04	16.73	74.54
4	1.40	11.61	86.15	1.40	11.61	86.15
5	0.74	5.92	92.07			
6	0.58	4.85	96.92			
7	0.46	3.08	100			

Extraction method: Principal component analysis.

Factor 1. Intent to Hurt

This factor included those responses in which adolescents considered the intent of causing social or psychological injury to others to be a necessary condition to classify cyberaggression as cyberbullying. This factor accounts for 38.57% of the variance (Table 1), it has an internal reliability of .72, and a mean factor loading of .51.

Factor 2. Imbalance of Power

This factor included behavior that the pupils classified as cyberbullying and in which they perceived the existence of an asymmetry between the aggressor and victim, not just social or psychological, but also regarding the mastery of technological media. This factor accounts for 19.24% of the variance (Table 1), has high internal reliability ($\alpha=.74$), and a mean factor loading of .53.

Factor 3. Advertising

This factor includes the situations in which adolescents indicated that there has to be dissemination of cyberaggression, through either the Internet or cellular telephony, as a necessary condition for it to be classified as cyberbullying. This factor accounts for 16.73% of the variance (Table 1), has a moderate internal reliability ($\alpha=.67$), and a mean factor loading of .47.

Factor 4. Form of Social Relationship

This factor includes cyberbullying situations that adolescents interpreted as a form of fun and relationship among peers. This factor accounts for 11.61% of the variance (Table 1), has a moderate internal reliability ($\alpha=.81$), and a mean factor loading of .50.

The factor extraction indicated that there are three key criteria that adolescents used to define cyberbullying: intent to hurt, imbalance of power, and advertising. Nevertheless, they attributed all three criteria simultaneously to impersonation (Table 2).

Table 2. Perception of cyberbullying. Rotated Component Matrix

	Components			
	1	2	3	4
Definition of cyberbullying	.649	.612	.476	
Threats	.388	.519		
Spreading false rumors			.520	.415
Insults			.401	.524
Exclusion	.479			
Impersonation	.506	.634	.307

The results also show that adolescents established a link between the intent and imbalance criteria to define threats and harassment as cyberbullying. But in neither of these modes of abuse is advertising a relevant criterion. Abuse associated with spreading rumors and insults is perceived simply as behavior that facilitates interaction and communication among peers. The content of the messages, as well as the consequences that they may have for others, are relativized and justified as part of adolescents' social dynamics, and seen as not necessarily going to harm others. Exclusion is interpreted as behavior aimed at inflicting harm on victims in which they feel rejected from groups (.479). The intent criterion is also present in the perception adolescents have of recording and disseminating acts of physical aggression (.442). Unlike exclusion, in physical aggression there is also a factor loading (.570) for the criterion of advertising. Therefore, this type of cyber abuse is described as cyberaggression that seeks to cause harm to others, and that this harm is intensified by the publication and dissemination of those recordings.

Identifying Cyberaggressors and Cybervictims

A total of 211 adolescents declared themselves to be victims of cyberbullying, and 245 claimed to be cyberaggressors. Table 3 presents the distribution of cyberaggressors and cybervictims by gender and education level (Table 3).

Table 3. Number of cyberaggressors and cybervictims by gender and education level

	Cybervictims					Cyberaggressors				
	1st ESO	2nd ESO	3rd ESO	4th ESO	Total	1st ESO	2nd ESO	3rd ESO	4th ESO	Total
Boys	18	16	27	22	83	50	44	27	29	150
Girls	23	27	35	43	128	19	38	17	21	95
Total	41	43	62	65	211	69	82	44	50	245

With respect to the variable corresponding to the type of aggressive behavior, the descriptive results show that cybervictims are subject to more than one form of cyberbullying, and aggressors do not use a specific type of cyber abuse to cause harm, but indicate a wide range of abusive behaviors, thus having a greater likelihood of causing the harm intended (Table 4).

Table 4. Number of cyberaggressors and cybervictims in the different modes of cyberbullying

	Cybervictims	Cyberaggressors
Threats	115	128
Spreading false rumors	151	102
Insults	110	94
Exclusion	73	52
Impersonation	71	83
Sexting	26	19
Physical attacks	30	16
Videoclip	139	157

The cyber abuses with the greatest prevalence of victims and aggressors were those related to the publication of humiliating images and videoclips, threats, insults, and spreading false rumors. The prevalence drops markedly when cyberaggression involves sexual harassment (sexting), recording and publishing physical aggression, and exclusion.

Similarities and Differences in the Perceptions of Cyberbullying among Cybervictims and Cyberaggressors

The analysis of the perceptions of cyberaggressors ($KMO=.76$, $Bartlett=.001$) and cybervictims ($KMO=.83$, $Bartlett=.001$) showed there to be four common factors regardless of the role that the adolescent plays: intent to hurt, imbalance of power, advertising, and forms of social interaction and relationships. Nevertheless, there were significant differences in the importance that the two groups attributed to each of those factors. For the aggressors, the primary factor is the imbalance of power, accounting for 30.32% of the variance of their responses. The second is advertising cyberaggression (variance=24.16%). The third is the factor corresponding to forms of social relationship (variance=20.84%), and the fourth is the intent to hurt (variance=10.73%). The pupils' responses yielded seven factors, four of which were significant (Table 5).

Table 5. Total variance explained by the four principal components: Cyberaggressors

Component	Initial eigen values			Extraction sums of squared loadings		
	Total	% of variance	Cumulative %	Total	% of variance	Cumulative %
1	3.27	30.32	30.32	3.27	30.32	30.32
2	2.81	24.16	54.48	2.81	24.16	54.48
3	2.16	20.84	75.32	2.16	20.84	75.32
4	1.34	10.73	86.05	1.34	10.73	86.05
5	0.89	7.68	93.73			
6	0.45	4.21	97.94			
7	0.22	2.03	100			

Extraction method: Principal component analysis.

For victims' responses, six factors explained the variability of their perceptions about cyberbullying and its various modes. Of these factors, four were significant. The primary factor is the intent to hurt, accounting for 41.16% of the variance. The second is advertising the aggression (variance=22.68%), the third is the imbalance of power (variance=13.80%), and the fourth is the factor corresponding to forms of social relationship (variance=9.37%) (Table 6).

Table 6. Total variance explained by the four principal components: Cybervictims

Component	Initial eigen values			Extraction sums of squared loadings		
	Total	% of variance	Cumulative %	Total	% of variance	Cumulative %
1	5.47	41.16	41.16	5.47	41.16	41.16
2	3.04	22.68	63.84	3.04	22.68	63.84
3	1.91	13.80	77.64	1.91	13.80	77.64
4	1.26	9.37	87.01	1.26	9.37	87.01
5	0.92	7.03	94.04			
6	0.74	5.96	100			

Extraction method: Principal component analysis.

These results showed that, while the intent to hurt is, for victims, the primary factor behind most of the cyberaggression analyzed, it is a factor of less importance for aggressors. Similarly, while the imbalance of power is a key component in the perceptions of aggressors, it is secondary in the case of victims. Other differences that stand out are how aggressors and victims apply these criteria to both the definition of cyberbullying and the determination of its various manifestations.

In cyberaggressors' perceptions, there are three identifying criteria they use to differentiate cyberaggression from an episode of cyberbullying: advertising (.431), intent to hurt (.534), and imbalance of power (.721), with most importance being given to this last criteria. Given this conceptualization, cyberaggressors only classified impersonation as cyberbullying as the only form of aggression that they simultaneously perceived as meeting the above three criteria (Table 7).

A detailed analysis of the factor loadings showed that aggressors believed that for five of the eight modes of cyberaggression analyzed to be manifested there must be an imbalance of

power between aggressor and victim (Table 7). Similarly, verbal abuse (rumors and insults), video-recorded abuse (physical aggression and videoclips), and impersonation are interpreted by aggressors as behaviors that promote communication and interaction among peers (Table 7). They see these behaviors as mechanisms of social interaction in which the game-playing component is clearly present, and the desire to cause harm is absent.

Table 7. The aggressors' perceptions of cyberbullying: Rotated Component Matrix

The advertising criterion is also one of the principal axes structuring aggressors' perceptions of the various modes of cyberbullying. The coincidence between the manifestations that these adolescents understand as being forms of social interaction and those which receive high factor loadings on the advertising criterion suggested that there is possibly a relationship of interdependence between the two attributes – in particular, that making certain behaviors publicly well-known increases the possibilities for social interaction among peers.

Victims' perceptions diverge significantly from those of the aggressor group. Although the criteria they use to define cyberbullying are only fully met in the case of impersonation as was also the case for aggressors, the factor loadings in the other modes of aggression clearly reflected different perceptions. The results for the intentionality factor showed that victims perceived all forms of cyber abuse considered in the present study except insults to be committed with the objective of causing harm to peers (Table 8).

Victims were more limited than aggressors in interpreting the different modes of cyberbullying as merely mechanisms of social interaction. Although the victims perceived that spreading hurtful rumors (.310) and the publication of offensive videoclips (.443) can sometimes be regarded as behavior that they and their peers regularly use in their cyber contacts and exchanges, they also noted that the reasons are not always just having fun or part of normalized interactions, but that in many cases there is the intent to hurt others (Table 8). On the contrary, they did not attribute insults with the intent to hurt. Rather, these are interpreted primarily as forms of greeting or expressions used to address peers, with there being no intention to cause any offense.

One final difference between victims and aggressors is that the former find little relevance in the imbalance of power criterion. While aggressors score this criterion in five of the eight modes of cyberbullying analyzed, victims only scored it in impersonation (.584). For them, this

imbalance is probably related to the possession of technical knowledge that allows the aggressor to hack into security systems and steal other people's identities, private messages, and documents.

DISCUSSION

Despite the proliferation of research on cyberbullying in the last decade, important questions remain about the conceptual definition of this phenomenon. The present results are consistent with the suggestions made by Slonje et al. (2013) about the need to consider in greater depth the delimitation of the criteria that define this construct. If researchers use different criteria to those used by youth to classify violent behaviour as cyberbullying then they will be describing different realities, and the success of anti-cyberbullying programs will consequently be severely threatened.. This is a population for whom the patterns of communication and interaction among peers differ from those of preceding generations. For them, ICTs form the essence of the instruments they use for connection and relationships with not only their closest sociocultural environment but also another virtually constructed environment to which they increasingly attach ever greater importance.

This study has shown that, of the five criteria considered to be identifiers of cyberbullying, Spanish adolescents have recourse to just three: intent to hurt, imbalance of power, and advertising. The lack of references to repeated aggressive behavior may be motivated, as noted by Nocentini et al. (2010), by the relationship between this criterion and advertising. Adolescents today understand that, even though the actual act of cyberaggression may occur only once, its rapid and uncontrolled spread via the Internet or mobile devices means that the hurt is repeated.

Spanish adolescents do not believe that anonymity should be considered a determining factor differentiating cyberaggression from an episode of cyberbullying. In line with these results, Dredge et al. (2014) argued that adolescents relativize this criterion because many of them know, or have reasonable suspicions about, the identity of aggressors. In most cases they are acquaintances who belong to the close environment of the victim. The high degree of

continuity between offline and online contexts in which adolescents' interactions foster the transfer to cyberspace of interpersonal relationships that started in physical environments (Subrahmanyam, Smahel, & Greenfield 2006). In this sense, cyberbullying episodes are a continuation of aggression experienced in the school context. The creation of peer support groups can promote the learning of how to resolve interpersonal conflicts, and the development of a capacity for empathy. The establishment and consolidation of a safety net in the form of presential adolescent support groups in classroom contexts, so important at this stage of a person's development, can foster the acquisition of prosocial attitudes and behaviors, and reduce instances of cyberbullying as well as encouraged the reporting of such instances.

Regarding the intent criterion, adolescents have no doubts about including it as a defining criterion of cyberbullying. Its high factor loading relative to those of the other factors showed that adolescents consider it to be a key identifier of cyberbullying, as has been noted in other studies (Bass et al., 2013). Nevertheless, there are still many unanswered questions concerning this criterion. One, for instance, is whether intent has to be detected in the aggressor or if it is sufficient that the victim perceives the abuse as causing them deliberate harm. In the cyber context, in which the aggressor's identity can be hidden, it is difficult to be sure that there is intent in the aggressive behavior. Thus, Dredge et al. (2014) suggested that the perception of intent may need to be replaced by the real impact that the aggression causes the victim. Other researchers argued that the understanding and relevance of the intent to harm as a determining factor of cyberbullying cannot be understood without relating this criterion with that of the imbalance of power (Nocentini et al., 2010).

The imbalance of power was the second most frequent criterion that the adolescents used to define cyberbullying. The high factor loading of this criterion is similar to that of the intent factor, and this could be indicative of the relationship of interdependence that Menesini et al. (2012) noted between the two. Nevertheless, more specific analyses will be required to determine the actual dynamics existing between these two dimensions.

Apart from its contribution to understanding the various perceptions of cyberbullying, the present study has provided information about the interpretation that adolescents make of the different modes in which this phenomenon occurs. In particular, the results showed that, taking as referent the definition that adolescents attributed to this construct, they only recognized impersonation or identity theft as being cyberbullying. For none of the other modes, do they transfer simultaneously the three criteria of intent, imbalance, and advertising, which, in their opinion, must concur for an act of cyberaggression to be classified as cyberbullying.

In this scenario, there appears to be another factor which we have termed 'forms of social relationship' showing that, for these adolescents, verbal (insults and spreading false rumors) and visual (publication of videoclips) aggressions, far from being interpreted as forms of cyberbullying, are considered to be mechanisms that foster and facilitate their communication and interaction. In this sense too, Straude-Müller, Hansen, and Voss (2012) noted that cyber verbal abuse is not only less serious but also sometimes goes unnoticed by adolescents since they have internalized and normalized these offensive behaviors as seemingly innocuous patterns of social relationship.

A second key contribution of the present chapter has been the analysis differentiating and comparing both the criteria aggressors and victims considered to be identifiers of cyberbullying and the interpretations they make of the different modes in which this phenomenon occurs. With respect to the definition of this construct, we observed that, although the two groups alluded to the same set of identifying criteria, those who commit the abuse emphasize the

imbalance of power criterion more. For victims, the contrary is the case, with intentionality being the primary factor, followed by advertising. Knowing the identity of the aggressor and the consequences that their actions have for the victim appeared to play a major part in understanding these results. Menesini et al. (2012) understand the imbalance of power not only as reflecting an asymmetry of status, but also as a dynamic of micro-processes of action and reaction. Thus, if the aggressor knows the consequences that their abusive actions have for the victim then this reinforces their perception of power. The decline in the score assigned to intent can be explained by the normalization that these adolescents make of their abusive behavior as prosocial patterns of interaction with their peers (Cuadrado 2012).

Slonje, Smith, and Frisé (2012) note the influence that knowledge of the aggressor's identity may have on the victim's perception of imbalance of power. If the identity is unknown then feelings of greater helplessness, frustration, and distrust undermine their possibilities of defense, putting them at a lower power status than the aggressor. Conversely, if they know or suspect who is behind the abuse then they can take some action to stop the aggression or mitigate its effects. A result is a reduction of the power asymmetry with the aggressor, since the victim has a perception of greater control (Sticca & Perren 2013).

With respect to the criterion of intentionality, victims perceive the abuse to which they are subjected as deliberate acts. The importance they assign to this criterion is reinforced when one considers the factor loading on the advertising component, since the public dissemination of the aggressions followed an uncontrolled path which causes the victim to continually experience the harm involved and to feel that so much suffering cannot be due to mere fortuitous events.

In the study of the modes of cyberbullying, it was only impersonation that we found victims and aggressors simultaneous attribution of the intent, imbalance, and advertising criteria. According to Vandebosch and Van Cleemput (2008), the other modes can be classified as cyber-teasing or cyber-arguing, in which either the intent to hurt or the imbalance of power component is lacking. Other researchers qualify them as forms of cyber-aggression (Pieschl et al., 2013). But, regardless of the name given to aggressions that do not meet the criteria the adolescents use to define cyberbullying, the present results showed that there are significant differences in aggressors' and victims' perceptions of the abusive behavior that researchers categorize as modes of cyberbullying.

One difference is in the types of abuse in which the two groups involved perceived the presence of an imbalance of power. The aggressors believe that five of the eight modes of cyber abuse studied require the aggressor to be superior to the victim, usually in the sense of a perception of greater control and security. Victims, however, only attribute this component to impersonation, thus demonstrating that, a priori, despite suffering abuse, they do not perceive themselves as weaker or more helpless than their peers, but instead that anyone may be susceptible of becoming a victim.

Another significant difference lay in the value given to the intent to hurt criterion. The aggressors only perceived intent to hurt in sexual harassment or impersonation. They seem to interpret the rest of the behaviors as inoffensive ways in which they interact with their peers. These results illustrate the existence of distorted perceptions of reality, of a lack of social skills, of unassertive models of coexistence inherited from the family context or their peer group, and an imbalance in their moral development which makes it difficult for them to understand the seriousness of their actions and the harm they cause to others (Pozzoli, Gini & Vieno 2012). On the contrary, victims perceived the intent to hurt in all the modes of abuse except insults.

This is probably a reflection of the suffering they have experienced or are experiencing in being subjected to those modes of abuse. Nevertheless, in two of these modes (rumors and videoclips) the intent to hurt is sometimes diluted to the extent that victims interpret these behaviors as forms of peer relationships. This perceptive duality may be motivated by the influence of the social context. Depending on the environment in which the adolescent finds themselves, or the people with whom they interact, cyberaggressive behaviors may be perceived either as normalized behavioral patterns or as deliberate acts intended to cause harm.

Finally, with respect to the advertising criterion, both aggressors and victims explained and justified most manifestations of cyber-abuse by their dissemination. If these acts are not advertised, they will probably be replaced by other acts of aggression in physical contexts and in the presence of witnesses, because, as observed by Saino, Veenstra, Huitsing, and Salmivalli (2011), the public plays a key role in the onset and persistence of bullying and cyberbullying.

The present results can be used to improve the intervention and prevention of violent behavior. In this sense, it must be noted that these programs need to place particular emphasis on modifying adolescents' maladjusted perceptions concerning interpersonal relationships, on intervening in attributional styles, and on developing awareness of the potential consequences of their actions for people who do not share their ways of relating to others. In light of the results of the study, our proposal focuses on the importance of considering cognitive and emotional mediation of the subject in whichever of the roles. This would allow direct intervention on the victim's internalization of the bullying, on the aggressor's distorted thinking and moral imbalance, and on the witness's difficulty in overcoming the fear of exclusion. For the optimization of this prevention and intervention, it would be advisable to consider involving those members of the community who are most significant for the adolescent (family, friends, school), since the behavior of these young people extends across all their social environments.

²Beykent University

INTRODUCTION

Increases in electronic and computer-based communication and information sharing have drastically changed the ways of social communication, learning, and entertainment. For billions of people around the world, the Internet has become an essential component of everyday life. In addition, more than 97% of youths in the United States have internet access (Tokunaga, 2010, Ybarra, 2004). Besides the many benefits associated with internet and technology access, problems arise regarding misuse, with the intention of causing harm to others as a form of misuse. Utilizing the internet and technology, bullies can harass their victims over a prolonged period (both inside and outside of the school), and they can maintain a high level of anonymity while harming others. By hiding their identity, bullies can potentially escalate their level of intimidation beyond that seen in traditional bullying.

In recent years bullying through electronic means, specifically mobile phones or the internet, has emerged, often labelled “cyberbullying.” One definition of cyberbullying is: “An aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself” (Smith et al. 2008, page 376).” Examples of what constitutes cyberbullying may include the use of media, such as blogs and social networks. Furthermore, it can include anonymous mobile phone calls, e-mails containing viruses from senders, password theft, and text messages which include insults, threats, and slander using sound, images, or textual formats. Arslan et al. (2012) found that, the majority of victims (nearly 80 percent) were unaware of the identity of the person bullying them, in keeping with the previous work by Kowalski and Limber (2007). A further concern was that around three quarters of the victims in this sample had not told anyone

* Corresponding Author’s Email: sevdaarslan@duzce.edu.tr.

about their bullying experiences, in line with some previous evidence as stated before. According to Ayas and Horzum (2012) some victims are concerned that disclosing the bullying experience will lead to a loss of their Internet or cell phone access. This finding emphasizes the need to educate children about cyberbullying and to provide appropriate support and prevention strategies at home and school.

A behavior can be considered bullying if it meets certain criteria, including repetition, intentionality, and an imbalance of power. These criteria were also initially used to conceptualize cyberbullying. Therefore, initial studies about bullying were focused on understanding more about the nature of cyberbullying and aimed at determining the similarities and differences when compared to traditional peer bullying. Previous studies revealed two different perspectives. Some researchers claimed that cyberbullying was not a new phenomenon and conceptualized it as an extension of the traditional bullying. Other researchers argued that, although cyberbullying shares some similarities with traditional bullying, there are different dynamics associated with cyberbullying, and that cyberbullying was a phenomenon with new, specific features.

Cyberbullying causes major problems among children, ranging from school failure to suicide in countries, such as the United States, England, and South Korea, that use the internet extensively and have advanced technology infrastructure. Researchers also indicates that cyberbullying has become a problem in Turkey (Erdur-Baker & Kavşut, 2007; Peker & Eroğlu, 2010). Cyberbullying has gained a lot of attention as children and adolescents can be subjected to cyberbullying in any setting and at any time. In addition, Li's (2006) study revealed that cyberbullying can occur among children and adolescents who attend the same school.

The studies reported in this chapter include prevalence rates of cyberbullying perpetration and cyber victimization, and these rates vary among these studies. These can be attributed to differences in sample characteristics and the assessment tools used to measure cyberbullying. The purpose of this chapter is to review literature on the age-related differences in cyberbullying. To do this, the chapter begins with a description of cyberbullying prevalence rates among elementary school children, followed by a section on prevalence rates among middle and high school students. The third section reviews literature on the prevalence rates of university students' cyberbullying involvement. Rates from different countries are discussed, with specific attention on Turkey.

EXAMINATION OF CYBERBULLYING EXPERIENCES AMONG DIFFERENT AGE GROUPS

Cyberbullying is universal, as it can happen to anyone, at anytime, and in any place, regardless of age; therefore, we can conclude that cyberbullying is a pervasive issue that can potentially impact all children, adolescents, and adults using the Internet. The majority of the cyberbullying research focuses on children and adolescents, but cyberbullying can occur among older age groups. Some studies have found no associations between age and cyber victimization status (Beran & Li, 2007; Patchin & Hinduja, 2006; Smith et al. 2008; Wolak et al. 2007; Ybarra). Other research suggests that the risk of being a cyber victim increases with age. In one set of studies, Kowalski and Limber (2007) and Ybarra et al. (2006) found positive correlations between age and victimization in their studies which examined 11 through 14 year olds and 10

through 15 year-olds. Mesch (2009) found that the average age of cyberbullied youths was higher than the average age of those who were not bullied. In contrast, Slonje and Smith's (2007) results revealed an inverse relationship between age and cyber victimization in their sample of 12 through 20 year-olds, which indicates that younger age groups were more often victims than the older age group. Taken together, these studies might suggest that cyberbullying increases from middle childhood to adolescence, with declines from adolescence into adulthood. These differences might be attributed to changes in web usage style as children grow older. This section of the chapter reviews literature on cyberbullying perpetration and cyber victimization rates among elementary, middle and high school, and college students.

CYBERBULLYING AMONG ELEMENTARY SCHOOL STUDENTS

Previous studies on cyberbullying have focused mostly on adolescents aged 14 years and above. Few studies have included younger children. In one of these studies, Aricak et al. (2008) found that younger children were at a greater risk of being bullied, whereas older children were more frequently the aggressor. In a US sample of 3,767 secondary school students (aged 11-14), 22% of the sample were victimized, 4% bullied other children, and 7% was both cyberbully and cybervictim (Kowalski & Limber, 2007). Another study published that year, Williams and Guerra (2007) included children as young as age 10 and as old as age 14 ($N = 3,339$). Their findings revealed that physical bullying and cyberbullying peaked in secondary school and declined in high school.

With even younger children (ages 8-11 years old; $N = 372$), Arslan et al. (2012) found that 27% had been victims of bullying via the Internet or mobile phones, 18% had been involved as cyberbullies, and 15% were both cyberbullies and cybervictims. Boys were significantly more likely to be cyberbullies than girls. This finding suggests that boys have a greater tendency towards aggressive behavior, even in a potentially anonymous online environment. In Turkey, this gender difference may be exacerbated as aggressive behavior may be more tolerated in boys. This finding contrasts with claims that cyberbullying is a 'relational' or verbal form of aggression and thus would be more common among girls. Girls and boys were equally likely to be cybervictims. They also explored features associated with home and school life that might put the children at risk for cyberbullying. Cyberbullying exposure (as both a bully and a victim) was significantly associated with lower levels of self-reported school achievement. Paternal unemployment was also associated with a three-fold increase in the likelihood of being a cyberbully. Children below average levels of school achievement were over three times as likely to be victims of cyberbullying as those with above average achievement. Low school satisfaction was also associated with a doubled risk of victimization. The number of siblings, caregiver status, and maternal employment were not significant predictors of being a cybervictim.

CYBERBULLYING AMONG MIDDLE AND HIGH SCHOOL STUDENTS

Many researchers divide adolescence into three periods. These include "early adolescence" (between ages 10-13 years old), "middle adolescence period" (between ages 14-17 years old), and "late adolescence" (age 18 and over). Generally, the focus in this section are individuals

between 10 and 18 years old. In one study, Price and Dalglish (2010) found that among 548 Australian students between the ages of 10-16 that 48% of the students between the ages of 10 and 12, 52% between the ages of 13 and 14, and 29% between the ages of 15 and 16 were cyberbullied. Ferdon and Hertz (2007) examined rates of cyberbullying among high school students, and around 34% were cyberbullies and 21% were cybervictims. Ybarra et al. (2007) focused their attention on school-based and lifetime prevalence rates of cyberbullying. They reported that 23% of the students in their sample were cyberbullied at school, 19.7% were cyberbullied at least one time in their life, and 54.4% were cyberbullied by others at least one time in their life. Other research has found that prevalence rates of adolescents' cyber victimization in their samples ranged from 4% (to 50% (Arslan et al. 2013; Kowalski & Limber, 2007; Li & Beran, 2006). Rates of cyber victimization also ranged from 11% to 13.6% (Arslan et al. 2013; Kowalski & Limber, 2007; Wang et al. 2009). Other studies have focused on occurrences of cyberbullying through different technologies. In this research, Arslan et al. (2015) found that 24.4% of cyberbullying among Turkish high school students occurred via e-mail, 8.5% in chat rooms, 35.4% via mobile phones, and 24.4% via MSN. Other research conducted by Price and Dalglish (2010) reported that 21% of the students were cyberbullied via e-mail, 20% through social media, and 19% via mobile phones. Previous findings in older children (aged 14 years and above) in Turkey have revealed ranges of cyberbullying (4 to 36%) and victimization (6 to 32%) estimates (Arslan et al. 2013; Arslan et al. 2015; Ayas, 2011; Erdur-Baker & Kavşut, 2007; Erdur-Baker, 2010; Özdemir & Akar, 2011).

Gender differences have also been explored in studies with adolescence. Arslan et al. (2015) showed that boys cyberbully (bully) more than girls and that they were also victimized by cyberbullying more often than girls. This research was corroborated previously by Li and Beran (2006), Wang and colleagues (2009), and Williams and Guerra (2007). In terms of victims, both sexes were comparably likely to have experienced cyberbullying (Arıcak, 2009). Kowalski and Limber (2007) argued that cyber-bullying is more common among the female students because relational bullying more common among the girls.

Prior studies have shown that the roles played by younger adolescents involved in cyberbullying whether as bullies, victims, or combined bully/victim groups may have differential risks for psychiatric and physical comorbidity when compared to each other.

Some adolescents reported that they engaged in cyberbullying because they gained satisfaction or pleasure from hurting their victims (Varjas et al. 2010). While some cyber-perpetrators reported victimizing targets in order to feel better about themselves, others cyberbullied because they believed, as a perpetrator, they were provoked by their victims and sought revenge. In addition, some cyberbullies tormented their victims because they disliked the person or were jealous of them. Furthermore, some adolescents cyberbullied others just "for fun." Varjas et al. (2010) suggested motivational factors (internal motivators, external motivators) for high school students concerning their involvement in cyberbullying.

CYBERBULLYING AMONG UNIVERSITY STUDENTS

Cyberbullying is not just a phenoma that occurs among children and adolescents, but it is also common among university students (Arıcak, 2009; Mura, Topcu, Erdur-Baker, & Diamantini, 2011).

Cyberbullying and its effects on adolescents have been largely studied in middle and high schools, but less is known about cyberbullying in college students. Young adults and university students are frequent users of technology and they often lead the way in adapting new technologies for everyday use. College students can become highly competitive and political, and therefore they might be more likely to get involved in bullying incidents (Kokkinos et al. 2014).

The internet is one of the most popular communication channels among university students worldwide. Research has shown that involvement in cyberbullying is predicted by the time spent online and time spent using social networking sites among college and university students (Walker, Sockman, & Koehn, 2011).

Having a mobile phone connected to the internet is predictive of cyberbullying experiences among university students (Kokkinos et al. 2014).

In one of the earliest studies on college students, Walker, Sockman, and Koehn's (2011) findings revealed that 11% of their participants had experienced cyberbullying with more than 40% knowing someone who had been cyberbullied.

In more current research, Ellen et al. (2015) indicated that 27% of the participants in their sample had experienced cyberbullying in college, which impacted their mental health, with 17.4% reporting depression and 37.5% meeting the criteria for alcohol abuse. Cyberbully-cyberbervictims reported the most psychological symptoms, suicidal ideation, more psychopathic traits, and were higher sensation seekers compared to perpetrators and cyberbervictims only. Higher rates were reported by Kokkinos et al. (2014) found that 58.4% of their sample had participated in a cyberbullying incident as perpetrators, victims, and cyberbully-cyberbervictims.

Kokkinos et al. also found that cyberbullying was predicted by callous/unemotional and impulsive/irresponsible traits, depression, and internet use, as well as lack of social skills. In a study conducted in Turkey, Dilmaç's (2009) sample of university students reported that 22.5% of them were cyberbullied and 55.3% had been cyberbullied at least one time in their life. Prior experiences as a victim of cyberbullying in high school increased the risk for cyberbullying and cyberstalking in college, which suggests that students' roles in cyberbullying might be maintained from high school into college (Kraft & Wang, 2010; Zalaquett & Chatter, 2014). Research on college students' motivations for engaging in cyberbullying revealed that the top motivators were cyber sanctioning, power struggles, and entertainment (Rafferty & Vander Ven, 2014).

These statistics clearly indicate that cyberbullying is a problem among college students. However, the majority of college students are handling cyberbullying incidents themselves rather than utilizing campus resources, but two-thirds of respondents would be more likely to consider reporting an incident if there was a central e-mail address available for reporting incidents. In an effort to prevent cyberbullying, colleges and universities must implement programs to advocate for awareness of this phenomenon (Ellen et al. 2015). Campus administrators should consider allotting financial resources to cyberbullying education and promote healthy ways to communicate and deal with conflict. Campus policies should be developed to deal with the instances of cyberbullying on college campuses.

CONCLUSION

A new generation of internet users has emerged within the last decades who have different behavior and discourse patterns, defining themselves in a new way based on their relationship in social and physical environments. This generation unlike the previous one had an option to have access to information anytime, anywhere, and in an interactive way and aimed to design and form a new life by the help of internet technologies. However, mobile phones, e-mail, use of blogs, social networking sites, and web pages may also ease the person to be involved in cyberbullying. Sending messages rapidly to thousands of people in order to hurt, insult, and threaten became easier with the opportunity to hide the perpetrator's real identity. In addition, development of this technology requires less time, energy, and all actions can be transmitted immediately via mobile phone and internet. Although it seems that all physical barriers in communication have disappeared between people, these technologies may negatively impact lives.

Internet technologies allow children and adolescents to be exposed to pornographic pages, games containing inappropriate material, discourses that incite sex, racial discrimination, and exalted vandalism. Internet addiction has now been identified as a new psychological problem. Virtual worlds also make it more difficult for children to distinguish the real and dream world. Adverse reactions can be observed in cyberbullied children, adolescents, and college students, like academic underachievement, psychological problems, familial conflict, social problems, and suicide (Erdur-Baker & Tanrikulu, 2010). Recent research suggests that cyberbullying is related to anger, aggression, and rule-breaking behaviors and cause behavioral and psychosocial problems. Due to these implications and negative consequences that cyberbullying behaviors might have on victims, cyberbullying must be considered a mental and public health issue.

INTRODUCTION

Research findings over the decade suggest that cyberbullying has become a major concern among children and adolescents across many nations, including Austria (Gradinger, Strohmeier, & Spiel, 2010), Spain (Del Rey, Elipe, & Ortega-Ruiz, 2012), Sweden (Laftman, Modin, & Östberg, 2013), Canada (Bonanno & Hymel, 2013), Australia (Campbell, Spears, Slee, Butler, & Kift, 2012), and the United States (Bauman & Newman, 2013), confirming that this behavior is indeed a global issue threatening the well-being of young people from elementary school to university. Turkey is one of these countries where cyberbullying has been regarded as an urgent issue, particularly after the publication of the first known Turkish study by Erdur-Baker and Kavşut (2007). Other Turkish studies confirmed that many Turkish youngsters are involved in some form of cyberbullying, either as a bully, a victim, or both bully and victim (e.g., Erdur-Baker, 2010; Topcu & Erdur-Baker, 2010; Topcu, Erdur-Baker, & Capa, 2008). Concerns about the negative consequences associated with cyberbullying were substantiated by other Turkish studies (e.g., Erdur-Baker & Tanrıkulu, 2010; Şahin, Aydın, & Sarı, 2012). These Turkish studies suggest close relationships between cyberbullying experiences and psychological issues, such as low self-esteem, high levels of depression (Chang et al., 2013), anxiety (Şahin et al., 2012), poor subjective health (Laftman et al., 2013), and internalizing difficulties (Bonanno & Hymel, 2013).

Unlike, traditional bullying, which peaks around middle school age (Olweus, 1993) and decreases as age increases (Nansel et al., 2001), cyberbullying is common among all age groups, including university students (Brack & Caltabiano, 2014; Doane, Pearson, & Kelley,

2014; Francisco, Simao, Ferreira, & Martins, 2015; Ojedokun & Idemudia, 2013; Kokkinos, Antoniadou, & Markos, 2014; Mura, Topcu, Erdur-Baker, & Diamantini, 2011; Xiao & Wong, 2013). Similar to children and adolescents, university students' cyberbullying victimization is related to serious psychological issues. In particular, Faucher, Jackson, and Cassidy (2014) found that university students who experienced cyber victimization had poor mental health (i.e., anxiety, depression, emotional outbursts), problems with personal relationships inside and outside university, poor academic performance (i.e., inability to complete assignments, lower grades, desire to leave school, missing classes), and poor physical health (i.e., emotional and physical insecurity, headaches, pains). They also had suicidal thoughts, considered harming themselves, and felt vengeful as a result of being exposed to cyberbullying victimization. These outcomes were confirmed by the findings of other research conducted with university students (e.g., Crosslin & Crosslin, 2014; Munawar, Inam-ul-aq, Ali, & Maqsood, 2014; Schenk & Fremouw, 2012; Smith & Yoon, 2013). In a qualitative study, Rivituso (2012) examined victims of cyberbullying, and they reported being fearful, losing trust in people and technology, blaming themselves for their victimization, felt vulnerable and stressed, and became frustrated and ashamed. Furthermore, Schenk, Fremouw, and Keelan (2013) examined university students who identified themselves as cyberbullies or cyberbully-victims, and they found that these students had higher levels of depression, hostility, sensitivity to interpersonal rejection, paranoia, aggressiveness, phobic anxiety, and psychoticism in addition to suicidal ideations/behaviors and illegal acts, such as violent crimes and drug crimes, in comparison to uninvolved university students.

The negative consequences related to cyberbullying have alerted researchers to the profiles of victims in order to design prevention and intervention programs to help children and adolescents better cope with cyberbullying (Bastiaensens et al., 2014; DePaolis & Williford, 2014; Lee, Zi-Pei, Svanström, & Dalal, 2013; Ortega-Ruiz & Nunez, 2012; Topcu, 2014; Topcu, Yıldırım, & Erdur-Baker, 2013). However, another strategy to help cyber victims is to also focus on cyberbullies, and identify their characteristics so that effective intervention and prevention programs can be achieved. However, relatively less research has focused on the cyberbullies compared to cyber victims. Among these studies, the findings suggested that cyberbullies were more likely to be frequent and risky computer users (Mishna, Khoury-Kassabri, Gadalla, & Daciuk, 2012), abuse their dating partners (Yahner, Dank, Zweig, & Lachman, 2015), carry a weapon (Mitchell, Ybarra, & Finkelhor, 2007), and not to attend school (Ybarra, Diener-West & Leaf, 2007). Furthermore, studies have indicated that cyberbullies are more likely to be traditional bullies regardless of their age and gender (Erdur-Baker, 2010). Therefore, this chapter aimed to identify the interrelationships among cyberbullies' gender, moral disengagement, and offline aggression. These two variables were chosen based on the previous studies that found that male cyberbullies were more morally disengaged (e.g., Bussey, Fitzpatrick, & Raman, 2015) and more aggressive in the face-to-face context (e.g., Renati, Berrone, & Zanetti, 2012) when compared to female cyberbullies. The current study tested a mediation hypothesis in which moral disengagement and aggression were expected to be mediating variables in the relationship between gender and cyberbullying perpetration.

Gender and Bullying

Among all variables, gender appears to be a salient variable deserving closer examination. In the aggression literature, gender differences are found in the manifestation of aggressive behaviors (Borsa, Damasio, Bandeira, & Gremigni, 2013). While males are found to be more directly and physically aggressive, females were generally reported to prefer indirect types of aggression (Björkqvist, Lagerspetz, & Kaukiainen, 1992; Kerestes & Milanovic, 2006). Because cyberbullying is considered a specific type of aggression, gender differences might be expected. Nevertheless, research results are inconsistent. One group of studies have not found any gender differences in terms of being a cyberbully (Balakrishnan, 2015; Patchin & Hinduja, 2006; Tokunaga, 2010; Williams & Guerra, 2007; Ybarra & Mitchell, 2004). As an explanation of no gender differences, Robson and Witenberg (2013) proposed that young people, regardless of gender, are immersed in online technologies daily, and that both females and males engage in cyberbullying equally as they have the same opportunity to engage in these behaviors due to their daily usage of technology. Another group of researchers have found that females were more likely to cyberbullying others. For example, Beckman, Hagquist, and Hellström (2013) found that females cyberbullied others at equal rates as males, and that females were also more likely to be cyberbully-victims when compared to the males. Other studies have also documented that females were more likely to be cyberbullies compared to the males (Connell, Schell-Busey, Pearce, & Negro, 2014; Rice et al., 2015). The indirect and relational nature of cyberbullying has been suggested as one of the possible reasons for why females cyberbully others more than males (Smith et al., 2008). Another possible reason for why females are more likely to cyberbully others is that females might engage in behaviors online that they never would do offline because of online disinhibition (Ybarra & Mitchell, 2004). A third group has found that males were perpetrators of cyberbullying significantly more than the females (Calvete, Orue, Estevez, Villardon, & Padilla, 2010; Doucette, 2013; Huang & Chou, 2010; Lapidot-Leffler & Dolev-Cohen, 2014; Li, 2006; Slonje & Smith, 2008; Wong, Chan, & Cheng, 2014). Huang and Chou (2010) speculated that males were cyberbullies more often because they were found to utilize information and communication technologies more frequently and more skillfully. However, it should be noted that these explanations have not been substantiated with empirical studies.

Conflicting patterns with regards to which gender is more likely to cyberbully others are also documented by Turkish studies. However, a male dominance in cyberbullying perpetration has been consistently and quantitatively observed in the Turkish cyberbullying literature. Only a few studies have not found gender difference in cyberbullying involvement (Topcu et al., 2008) and reported that females were significantly more likely to be cyberbullies (Erdur-Baker & Tanrikulu, 2010; Eroğlu, Aktepe, Akbaba, Işık, & Özkorumak, 2015).

On the other hand, the majority of findings from Turkish studies indicated that males cyberbullied others more often than females (e.g., Akbulut & Erişti, 2011; Baştürk-Akca, Sayımer, & Erdegül, 2015; Ekşi, 2012; Erdur-Baker, 2010; Erdur-Baker, 2013; Erdur-Baker & Kavşut, 2007; Erdur-Baker & Topcu, 2009; Karabacak et al., 2015; Ozden & Icellioğlu, 2014; Tanrikulu, Akbaba-Altun, Erdur-Baker, & Yerin-Güneri, 2015).

Because of the tendency for Turkish studies to report that males were more often cyberbullies when compared to females, researchers began to propose explanations that might account for gender differences in cyberbullying perpetration. One of the most widely discussed variables is gender socialization (Erdur-Baker, 2010; Topcu & Erdur-Baker, 2012; Wade &

Beran, 2011). Ferree and Hall (1996) described gender socialization as ‘ongoing, multi-level processes of social expectations, control, and struggle that sustain and subvert gender systems’ (p. 935). The socialization processes of females and males occur in different ways because societies expect each gender to conform to their specific norms, behaviors, values, and beliefs. This reasoning seems to have been supported by Agatston, Kowalski and Limber’s (2007) findings. In their study, while their female participants acknowledged that cyberbullying posed harm to people, males did not agree about the harmfulness of cyberbullying. This finding implied that males consider cyberbullying behaviors more acceptable compared to the females. A similar explanation supporting the role of gender socialization in cyberbullying experiences of Turkish university students was provided by Akbulut and Erişti (2011). They noted that, although females are expected to conform to societal rules, males are not, due to Turkish society’s dominant patriarchal nature. This may trigger males’ tendencies to assume more bully roles.

Participants’ characteristics, the measurement tools utilized, and methodologies employed might be explanations for divergent findings regarding gender differences in cyberbullying. Undertaking such a task might be incredibly difficult, and therefore a more fruitful direction might be to examine underlying variables which might account for these differences. One of the very few studies scrutinizing the underlying factors contributing to gender difference in cyberbullying behavior examined empathy as a potential mediating factor (Topcu & Erdur-Baker, 2012). The findings revealed that when females scored higher in empathy they had lower levels of cyberbullying perpetration. Another study (Erdur-Baker & Akbaba-Altun, 2010) focused on risky Internet use as having a mediating role in the relationship between gender and the engagement in cyberbullying. The results revealed that male students were more likely to report experiencing cyber bullying and engage in risky internet activities. That is, risky internet use substantially mediated the gender differences in both cyber bullying and cyber victimization. Thus, empathy and safe Internet use could be two factors that differ between genders and as a result yield in divergent cyberbullying prevalence rates for two genders.

Differences in aggressive tendencies between males and females seem to have a role in their likelihood to cyberbully others. In general, aggression is defined as ‘any behavior directed toward another individual that is carried out with the immediate intent to cause harm’ (Anderson & Bushman, 2002, p. 28). Although the existence of a relationship between gender and aggression has been reported, the research findings are inconsistent about whether males or females are more aggressive (Archer, 2004). While males were found to be physically more aggressive than females, a contradiction is present as to whether females or males are more relationally, indirectly, and verbally aggressive (Archer, 2004). A similar conflict seems to exist in cyberbullying perpetration. While some studies indicate that males cyberbullied others more than females (e.g., Kokkinos et al., 2014), other studies have found the opposite pattern (Beckman et al., 2013; Connel et al., 2014; Erdur-Baker & Tanrıkulu, 2010; Holfeld & Grabe, 2012; Rice et al., 2015; Smith et al., 2008). Moreover, the relationship between gender and cyberbullying perpetration was found to be moderated by age based on a meta-analysis study by Barlett and Coyne (2014). The findings of this meta-analysis indicated that during early adolescence females scored higher in cyber bullying than males; however, in late adolescence males reported that they cyber bully others more than females. According to Barlett and Coyne (2014), researchers theoretically expect that if cyber bullying is an extension of traditional bullying, males are more likely to cyberbully others. However, if cyber bullying is conceptualized as a form of relational or indirect aggression, females might possibly engage in

more cyberbullying. Studies assessing the role of aggression in cyberbullying perpetration have reported that higher levels of proactive and reactive aggression (Renati et al., 2012) and verbal aggression (Roberto, Eden, Savage, Ramos-Salazar, & Deis, 2014) were associated with being a cyberbully. In sum, gender appears to be an important variable in understanding predictors of cyberbullying perpetration. However, the existing knowledge about the nature of such gender differences is limited, especially among university students.

Moral Disengagement and Cyberbullying

Moral disengagement is described as the cognitive processes used to justify harmful behaviors, which normally do not conform to one's internal moral standards (Bandura, 2002). According to Bandura (2002), while moral disengagement does not develop in the early years of life, males tend to become more morally disengaged as time passes. The underlying reasoning behind this transition may be related to gender socialization. Given that practices of moral disengagement are inherently engraved in the social systems (Bandura, 2002), males might develop more moral disengagement because morally disengaged actions could be more tolerated for males than females within male-oriented societies, such as Turkey (Kocacık, Kutlar, & Erselcan, 2007). Even though studies investigating the role of moral disengagement in cyberbullying perpetration among other groups have been few in number, they have frequently reported that cyberbullies tend to have higher levels of moral disengagement (Bussey et al., 2015; Renati et al., 2012; Robson & Witenberg, 2013; Wachs, 2012). As a personality trait, moral disengagement provides cyberbullies with a cognitive schema to convince themselves that harming others, which would normally be against their personal moral standards, is tolerated in certain situations or contexts. Cyber bullies, in order to make their harmful behaviors acceptable, may employ a reason for harming victims, such as victims deserve it or victims need to learn a lesson. Furthermore, cyber bullying behaviors occur through cyber platforms where physical contact is not possible, and the impact on the physical and psychological wellbeing of victims cannot be observed. These inabilities might provide rationales for cyberbullies to justify their damaging behaviors since nobody physically gets hurt as a result of their bullying perpetration. To our knowledge, no research has examined the mediational role of moral disengagement regarding the associations between gender and cyberbullying perpetration. Therefore, this chapter aims to explore whether the level of aggression and moral disengagement explains gender differences in cyberbullying perpetration among university students. Based on previous studies on aggression and moral disengagement, it was hypothesized that males would be more likely to engage in cyberbullying perpetration due to their greater levelsof aggression and higher levels of moral disengagement when compared to their female counterparts.

METHOD

Participants

A total of 632 university students participated in this study. Of the participants, 365 (57.8%) were female and 267 (42.2%) were male. The participants were between the ages of

18 and 28 ($M = 21.31$; $SD = 1.89$). Among the participants, 19.3% ($n = 122$) were in an English preparatory school, 18.5% ($n = 117$) were freshmen, 11.9% ($n = 75$) were sophomores, 18.0% ($n = 114$) were juniors, and 31.8% ($n = 201$) were seniors (three participants did not report their year level). Concerning parental educational levels of the participants, 4.9% ($n = 28$) of their mothers were not educated, 66.6% ($n = 421$) completed high school, and 26.4% ($n = 167$) received a college degree. Thirteen participants (2.1%) did not report their mother's education level. Participants reported that 0.8% ($n = 5$) of their fathers were not educated, 53.0% ($n = 335$) completed high school, and 44.2% ($n = 279$) received a college degree. Thirteen participants (2.1%) did not report their father's education level. While 17.4% of the participants were in the low income group (≤ 1500 Turkish Liras (TL/month)), 24.1% were in the high income group (≥ 3600 TL/month). Yet, most of them (58.5%) belonged to the middle income group ($1600 \text{ TL} \leq \text{monthly income} \leq 3500 \text{ TL}$). Participants mostly utilized laptops and smart phones to connect to the Internet, and a great majority of them (43.2%) spent 2-3 hours online every day. Characteristics of the sample can be seen in Table 1.

Table 1. Participants' Internet connection tools and Internet usage frequencies

	<i>f</i>	%
*Tools		
Laptop	568	90.0
Smart phone	511	81.0
PC	183	29.0
Tablet PC	140	22.2
**Frequencies		
A few hours in a week	28	4.4
1 hour or less in a day	88	13.9
2-3 hours in a day	273	43.2
4-5 hours in a day	161	25.5
6 hours or more in a day	73	11.6

Notes. * Participants were able to choose more than one option; thus, the total percentage may exceed 100%. ** Nine participants (1.4%) did not report their daily Internet use.

Measures

Revised Cyber Bullying Inventory (RCBI) for University Students. The RCBI for University Students is a revision of the Revised Cyber Bullying Inventory developed by Topcu and Erdur-Baker (2010). It has a total of 12 items to assess cyberbullying experiences in two independent sections. The first section examined how frequently participants cyberbullied others in the previous six months, and the second section examined how frequently the participants were cyber victimized in the last six months. Because this study focused on cyberbullying perpetration, the cyberbullying perpetration subscale was only used in this current research. This measure is rated on a 4-point rating scale, with 1 = never, 2 = once, 3 = twice-three times, and 4 = more than three times. Sample items included: sending threatening, offending, embarrassing messages on the Internet, and swearing at others on online settings. Using the Amos 21 program, a confirmatory factor analysis (CFA) was carried out for

this chapter to test whether the cyberbullying perpetration section confirmed the one-factor structure solution. According to the results, CFA initially indicated a poor fit ($\chi^2 = 373.41$, $df = 54$, $p < .001$, $GFI = .91$, $CFI = .79$, $TLI = .74$, $SRMR = .06$, $RMSEA = .09$). Modification indices were checked, and the error covariances between some items were freely estimated, which improved the model fit ($\chi^2 = 200.25$, $df = 52$, $p < .001$, $GFI = .95$, $CFI = .90$, $TLI = .88$, $SRMR = .05$, $RMSEA = .06$), and confirmed the unidimensional factor structure for the cyberbullying perpetration section of RCBI for University Students. In addition, the inter-item reliability of the cyberbullying perpetration section of RCBI for University Students was .78.

P propensity to Morally Disengage Scale (PMDS). PDMS examined participants' inclinations to convince themselves that they may engage in unethical behaviors under particular conditions. It was originally developed by Moore, Detert, Treviño, Baker, and Mayer (2012), and it was adapted into Turkish by the first two authors of this chapter. PDMS includes eight items, and participants rated the items on a scale of 1 (strongly disagree) to 7 (strongly agree).

Higher scores indicated a higher level of moral disengagement. Sample items included: "Taking something without the owner's permission is okay as long as you're just borrowing it", and "People shouldn't be held accountable for doing questionable things when they were just doing what an authority figure told them to do". For this study, the findings of the CFA provided evidence for the one-factor structure of the PDMS ($\chi^2 = 70.13$, $df = 20$, $p < .001$, $GFI = .97$, $CFI = .91$, $TLI = .88$, $SRMR = .04$, $RMSEA = .06$). The inter-item reliability of the PDMS was .68.

The 12-Item Aggression Questionnaire (AQ-12). AQ-12 measures aggressive inclinations of the participants. AQ-12 was developed by Bryant and Smith (2001) by using the refined version of the 29-item Aggression Questionnaire (Buss & Warren, 2000). It was adapted into Turkish by the first two authors of this chapter. The items are rated on a scale of 1 (uncharacteristic of me) to 5 (extremely characteristic of me). The higher the scores, the more likely a respondent has a higher tendency of aggression. Example items included: "I have trouble controlling my temper", and "Sometimes I fly off the handle for no good reason". A unidimensional first-order factor structure, four-factor structure, and a single second-order factor structure are possible for the AQ-12. As aggression was assessed as an individual construct, a unidimensional first-order factor structure for the AQ-12 was preferred in this study. In the current study, CFA initially indicated a poor fit ($\chi^2 = 819.66$, $df = 54$, $p < .001$, $GFI = .81$, $CFI = .65$, $TLI = .57$, $SRMR = .10$, $RMSEA = .15$). Modification indices were checked, and the error covariances between some items were freely estimated. This resulted in a better goodness of fit ($\chi^2 = 293.59$, $df = 50$, $p < .001$, $GFI = .92$, $CFI = .89$, $TLI = .85$, $SRMR = .06$, $RMSEA = .08$). The inter-item reliability of the AQ-12 was .81.

Demographic Information Form. The demographic information form included participants' age, gender, grade level, monthly income level of parents, parental educational level, Internet connection tools, and Internet use frequency.

Procedure

Institutional ethics approval was acquired to conduct this study. By adopting a convenient sampling strategy, the data were collected during the spring semester of the 2013-2014 academic year from university students enrolled in a large, urban public university in the capital

of Turkey. An anonymous, self-report, paper-based survey was administered in classrooms. The goal of the study was verbally and in writing explained to the participants, and participation was strictly voluntary. Approximately 20 to 25 minutes were required to fill out the whole survey form.

Data Analysis

A correlation analysis was performed to assess the correlations among the study variables. A t-test analysis was conducted to evaluate gender differences regarding the study variables.

Finally, the multiple mediation analysis was conducted by using the INDIRECT macro for SPSS 22 (Preacher & Hayes, 2008). Bootstrapping procedure was used to explore the significance of the indirect effects in mediational models, because it does not require the normality assumption, and it is more powerful when determining mediating effects (Preacher & Hayes, 2008). Therefore, bootstrapping procedure was employed in this present study by adjusting the number of the bootstrap samples to 5.000 and the confidence interval (CI) to 95% as suggested by Preacher and Hayes (2008).

RESULTS

Preliminary Analyses

Table 2 presents the correlations among the study variables in addition to the means and the standard deviations of each variable. As anticipated, moral disengagement and aggression were significantly correlated with cyberbullying perpetration. In addition, gender was significantly correlated with cyberbullying perpetration, moral disengagement, and aggression. In order to examine whether there were significant gender differences, a series of t-tests were performed on the study variables. Bonferroni's correction was applied by adjusting the p-value to decrease the Type-1 error on multiple comparisons ($0.05 / 3 = 0.017$).

Table 2. Means, standard deviations and correlation coefficients of the study variables

	Females (N = 365)		Males (N = 267)		1	2	3	4
	M	SD	M	SD				
1. CB perpetration	14.12	3.52	16.39	4.86	-			
2. Moral disengagement	17.80	6.64	19.29	7.06	.28**	-		
3. Aggression	29.36	7.52	30.94	8.68	.34**	.32**	-	
4. Gender	-	-	-	-	.26**	.11**	.10*	-

Notes. CB refers to 'cyber bullying'. * $p < .05$; ** $p < .01$, two-tailed. Gender was coded for females = 1 and males = 2.

The results showed that males ($M = 16.38$, $SD = 4.86$) when compared to females ($M = 14.12$, $SD = 3.52$) had significantly higher scores on cyberbullying perpetration, $t(459.73) = -6.47$, $p < .001$, and they ($M = 19.29$, $SD = 7.06$) had significantly higher scores on moral

disengagement than females ($M = 17.80$, $SD = 6.64$), $t(630) = -2.70$, $p = .007$. Moreover, males ($M = 30.94$, $SD = 8.68$) had significantly higher scores on aggression when compared to females ($M = 29.36$, $SD = 7.52$), $t(630) = -2.45$, $p = .015$. In short, males' cyberbullying perpetration, moral disengagement, and aggression levels were significantly higher than females.

TESTING THE MULTIPLE MEDIATION MODEL

Due to the fact that moral disengagement and aggression were significantly correlated with gender and cyberbullying perpetration, a multiple mediation analysis was carried out to determine the total and specific indirect effects of the mediators (Preacher & Hayes, 2008). While the mediators were moral disengagement and aggression, the independent variable was gender and the dependent variable was cyberbullying perpetration.

Figure 1. Total and direct effects of the tested model. Note: * $p < .05$; ** $p < .01$, *** $p < .001$.

The total (non-mediated) effect of gender ($\beta = 2.26$, $SE = .33$, $t = 6.79$, $p < .001$) and the direct effect (together with the mediators) of gender ($\beta = 1.88$, $SE = .32$, $t = 6.01$, $p < .001$) on cyberbullying perpetration were significant (see Figure 1). According to the results of the mediation analysis, the total indirect effect of gender on cyberbullying perpetration through the mediators (moral disengagement and aggression) was significant ($z = 2.97$, $p < .01$). Moral disengagement ($z = 2.34$, $p < .05$) and aggression ($z = 2.31$, $p < .05$) were significant mediators of the relationship between gender and cyberbullying perpetration.

Table 3 details the estimates and the 95% CIs bootstrapped bias corrected (BC) as well as the bootstrapped bias corrected and accelerated (BCa). According to Preacher and Hayes (2008), BCa 95% bootstrap CI interval values should not include zero in order to get a significant result. In this current research, BCa 95% bootstrap CI interval for the total indirect effect was between .1442 and .6935, .0449 and .3589 for moral disengagement, and .0462 and .4468 for aggression. Therefore, the combined effects of moral disengagement and aggression mediated the relationship between gender and cyberbullying perpetration.

Table 3. Mediation of the effect of gender on cyberbullying perpetration through moral disengagement and aggression

				Bootstrapping			
				BC 95% CI		BCa 95% CI	
	Point estimate	SE	Z	Lower	Upper	Lower	Upper
Moral disengagement	0.1644	0.0702	2.3410*	0.0442	0.3582	0.0449	0.3589
Aggression	0.2207	0.0954	2.3125*	0.0462	0.4468	0.0462	0.4469
Total	0.3851	0.1295	2.9746**	0.1435	0.6933	0.1442	0.6935

Notes: While BC refers to bias corrected, BCa refers to bias corrected and accelerated. The number of bootstrap resamples was 5000. $R^2 = .20$. * $p < .05$; ** $p < .01$.

DISCUSSION

This chapter aims to shed light on the gender differences in cyberbullying perpetration. To help explain such differences, moral disengagement and aggression were examined as a possible explanation of gender differences in these behaviors. The results of this study revealed that both moral disengagement and aggression mediate the relationship between gender and cyberbullying acts. In this study, compared to females, males reported significantly higher scores on cyberbullying perpetration, moral disengagement, and aggression. This is consistent with the previous investigations reporting an association between being male and higher levels of cyberbullying perpetration (e.g., Wong et al., 2014), being male and moral disengagement (e.g., Bandura, 2002), and being male and physical aggression (e.g., Archer, 2004). These finding also imply that males might be more at risk in terms of engaging in more serious risky behaviors. In fact, previous research has provided evidence suggesting that higher levels of cyberbullying perpetration, moral disengagement, and aggression were potential contributors to risky behaviors for young people, such as suicide, anti-social behaviors, or health risk behaviors (Hinduja & Patchin, 2010; Hyde, Shaw, & Moilanen, 2010; Prinstein & La Greca, 2004). Specifically considering cyberbullying, this finding suggests that intervention and prevention strategies targeting the personality traits specific to each gender can be particularly helpful for males and females (Kowalski, Morgan, & Limber, 2012).

The results of mediation analysis revealed that being a male or a female was not an explanation for cyberbullying perpetration. However, it is the combined effect of moral disengagement and aggression that explains gender difference in cyberbullying perpetration. In addition, the unique contributions of moral disengagement and aggression were also explanatory in the relationship between cyberbullying perpetration and gender. That is, moral disengagement and aggression separately and in combination have roles in this relationship.

Even though higher levels of moral disengagement were previously linked to being a cyberbully (e.g., Bussey et al., 2015; Robson & Witenberg, 2013), to the best of authors' knowledge, the explanatory role of moral disengagement in gender differences regarding cyberbullying perpetration was identified for the first time in this chapter. Therefore, further investigations examining the mediator role of moral disengagement in the relationship between

gender and cyberbullying perpetration are needed to validate this finding. Unfortunately, there is no empirical data to confirm the study's findings regarding moral disengagement mediating the relationship between gender and cyber bullying perpetration. Nevertheless, there appears to be some support for these associations. In particular, Bandura, Barbaranelli, Caprara, and Pastorelli (1996) argued that higher levels of moral disengagement contribute to being more prone to engagement in aggression, and that males were more likely to develop greater levels of moral disengagement when compared to the females. According to Bandura (2002), while no significant gender differences in moral disengagement are present in the early years of life, males might become moral disengagers as they get older. A potential explanation for this change might be gender socialization. As activities of moral disengagement are inherent in social systems (Bandura, 2002), males, compared to the females, might behave more morally disengaged since their morally disengaged behaviors could be more acceptable in male-oriented societies, such as Turkey.

Cyberbullying is a relatively new type of peer aggression, and it might be expected that males with higher levels of moral disengagement prefer cyber environments where they can easily disclose their aggressive tendencies. Furthermore, cyber environments offer opportunities for morally disengaged bullies do to the removal of physical presence and anonymity. In addition, the immediate destructive impacts of bullying behavior and the physical and psychological responses of victims cannot be observed. Bandura et al. (1996) maintain that individuals are less likely to behave aggressively when they can personally observe their victims suffering or can directly impose pain on their victims. Therefore, cyberbullies are unable to witness the harm they cause on victims and victims' immediate reactions, potentially leading them to be motivated to behave more aggressively in cyber settings.

Extensive research has indicated that cyberbullies score lower on empathy, which serves as a preventive mechanism for inflicting harm on others (Renati et al., 2012; Topcu & Erdur-Baker, 2012). As suggested by past research (e.g., Topcu & Erdur-Baker, 2012), empathy training can potentially be helpful to enhance the moral reasoning abilities of cyberbullies, such as training to adopt others' perspectives or sharing others' feelings. In addition, computer software that reminds young individuals about the negative impacts of their cyberbullying perpetration behaviors seems to be useful in preventing cyber bullying. For example, the software '*Rethink*' developed and tested by Prabhu (2014) alerted online users to the potentially harmful and offending content of the messages they were about to send. *Rethink* software resulted in a significant decrease in sending harmful and offending messages, and prevented cyberbullying before it happened. Such software can be effective in decreasing moral disengagement levels of cyberbullies by making them aware of the negative influences associated with their bullying behaviors.

Similar to moral disengagement, aggression was also found to be a unique mediator of the relationship between gender and cyberbullying perpetration. Existing research has provided evidence that higher levels of aggression were associated with the engagement in cyberbullying (Renati et al., 2012; Roberto et al., 2014). However, the mediational role of aggression on the relationship between gender and cyberbullying perpetration had not previously been examined, and therefore more investigations should be conducted to corroborate this finding. A possible explanation for this finding might be the gender socialization process; while males learn that behaving aggressively might be tolerated for their gender, females encounter less tolerance for their aggressive acts than males. Relative to females, male cyberbullies may feel more

comfortable while behaving aggressively, including bullying others online. This speculation seems to be supported by an empirical study (Agatston et al., 2007), which reported that though females considered cyberbullying as a problem at school, males were not totally in agreement about cyber bullying's being a school problem. In other words, males did not consider behaving aggressively online as a serious problem. Therefore, since online aggression did not bother males very much, they might engage in cyberbullying more than females because of their higher levels of aggression. To reduce aggressive behaviors in educational and online settings, cyberbullying and anger management programs should be implemented as they have been found to be effective interventions intended for young people (Candelaria & Fedewa, 2012). In addition to anger management programs, interventions aiming to build emotional intelligence skills can be helpful for dealing with aggressive behaviors of youth, considering that individuals with greater levels of emotional intelligence behave less aggressively (Garcia-Sancho, Salguero, & Fernandez-Berrocal, 2014). Moreover, Johnson (2011) recommends educating cyberbullies to gain awareness about the impacts of their bullying behaviors on victims, and strengthening their self-esteem and social skills as well as teaching impulse control skills and expressing emotions.

Gender differences in aggressive behaviors, including cyberbullying, have been an important topic for the literature on aggression. Researchers have endeavored to understand whether males or females behave more aggressively. Yet, a consensus has not been reached so far because of inconsistent findings. Thus, future studies need to investigate explanations of gender differences in aggressive behaviors in order to be gender sensitive while planning prevention and intervention strategies.

For example, based on the current study's findings, personality traits seem to account for gender differences in cyberbullying perpetration among university students in Turkey. Therefore, future studies are warranted to contribute to the literature by considering which characteristics differ between males and females, and how these differences in personality traits impact cyberbullying perpetration.

Although the present study contributes to the literature by examining the mediating role of moral disengagement and aggression in gender differences in cyber bullying perpetration, there are some limitations. The findings of this chapter were restricted to only two of the possible personality traits of the cyberbullies: moral disengagement and aggression. Further research is necessary to investigate whether other personality traits have mediating roles in cyberbullying perpetration. Lastly, the gender socialization process for females and males seems to have an important impact on aggressive behaviors. Yet, the literature lacks empirical evidence to support the role of the gender socialization process on aggressive behaviors. Researchers have only speculated on its impact on the aggressive behaviors of males and females. Therefore, empirical studies are needed to validate its role in gender differences concerning aggression.

The findings of this study can only be generalized to a population that carries similar characteristics as those participants from the present study. In addition, this chapter relied on self-report data concerning cyberbullying experiences and personality traits. Self-report measures are subject to social desirability bias. Specifically, revealing sensitive information, such as cyberbullying perpetration, aggression, and moral disengagement, could be more difficult for some people and obtaining data from other sources such as peer reports or parent reports might lead to less biases concerning sensitive topics.

Another limitation of this study is its cross-sectional nature which prevents expecting a cause and effect relationship among the variables studied in this current research. Further

research could adopt a longitudinal design to test the same model over time in order to understand whether the established relationships are stable over time.

CONCLUSION

Cyber bullying as a new challenge in the lives of the technology cohort has led researchers to attempt to understand how adolescents experience this new type of bullying by examining the characteristics of cyber bullies and risk factors for being a cyber bully. Although it is still not clear whether one gender is more at risk of engaging in cyber bullying, the majority of Turkish literature indicated that males are more at risk of cyber bullying. In the present study, aggression and moral disengagement were tested as the potential explanatory mediating factors of males' dominancy in cyber bullying. As expected, males were found to be more aggressive and morally disengaged than females, and males scored higher in cyber bullying. Moral disengagement and aggression mediated the relationship between gender and cyberbullying perpetration acts.

Chapter 7

GENDER DIFFERENCES IN PEER-PRESSURED SEXTING

Elizabeth Englander* and Meghan McCoy

Bridgewater State University

INTRODUCTION

In 2008, Jessica Logan committed suicide after her nude photo circulated throughout her Ohio town (Celizic, 2009). The case focused international attention on the possibility that nude pictures could be sent electronically. Since 2008, digital behaviors in general have not decreased in frequency; in fact, digital technology use among youth has dramatically increased to become a primary method of communication. A number of more recent studies have found that a large majority of teens continually use digital devices and social media (Englander, 2011; Lenhart, Madden, Smith, Purcell, Zickuhr, & Rainie, 2011). Heavy digital use is found among all social classes (Rainie, Lenhart, & Smith, 2011). The ubiquitous use of text messaging does not seem to be a passing fad; in 2010, 44% of teens studied in Massachusetts listed “text messaging” as their preferred type of communication, and by 2014, that proportion had risen to 65% (Englander, In Progress). Digital communications are largely used for positive interactions but are also, without dispute, one vehicle for harassment and threat between youth. Compounding the complexity of this is the fact that the same digital behaviors can represent little threat or can alternatively be a mechanism for emotional and social trauma.

As an example, consider *sexting*, a digital behavior that is usually, but not uniformly, defined as *sending nude or sexually explicit photos of oneself through electronic devices to a peer*. Frequency data suggests that approximately 10% to 30% of children and teens admit to having sexted, with numbers for teens aged 16 and older hovering around the 25% to 40% range (Dake, Price, Maziarz, & Ward, 2012; Englander, 2013; Mitchell, Finkelhor, Jones, & Wolak, 2011; National Campaign to Prevent Teen & Unplanned Pregnancy, 2008; Temple & Choi, 2014). Sexting appears to be common; and in and of itself it may not always jeopardize public health. It is the community, social norms, and social *context* within which sexting occurs that

* Corresponding Author’s Email: eenglander@bridgew.edu.

determines whether the incident could be considered cyberbullying or even sexual harassment, and therefore whether it could be potentially harmful. To many, the link between sexting and cyberbullying may seem unclear, but there is a relationship between some types of sexting behaviors and coercion, pressure, or bullying. Private images can be used to target and harass the subject of the photo, through, for example, behaviors such as *slut shaming* (i.e., harassing someone as a result of real or perceived sexual behaviors), *revenge porn* (i.e., the unwanted distribution of photos after the end of a relationship), or simply through the unwanted distribution of photos that the sender intended to remain private. It appears that while these negative behaviors are a relatively uncommon outcome of sexting, our ongoing research at the Massachusetts Aggression Reduction Center suggests that some of those behaviors can probably be characterized as digital sexual harassment.

This chapter reviews research findings from a 2013-2014 study of 642 college freshman recruited from the University's Subject Pool. This study surveyed subjects about many digital behaviors, including how sexting can occur because of digital sexual harassment, or how it can actually contribute to cases of digital sexual harassment.

A phenomenon that is of particular interest is called *pressured sexting*. Much sexting occurs willingly between two teenage partners in an emotionally intimate relationship, but in other cases, youth are blackmailed, threatened, or pressured into sexting (Englander, 2012; National Campaign to Prevent Teen & Unplanned Pregnancy, 2008; Zweig, Dank, Yahner, & Lachman, 2013). This chapter will examine some of the findings from that study, including the contexts in which sexting might increase vulnerability to digital sexual harassment.

BACKGROUND

Peer Pressure

There is a growing body of research examining the impact of pressure from peers or romantic partners on sexual behavior. Peer pressure involves groups or individuals influencing the attitudes and/or behaviors of others through the use of methods such as coercion, teasing, bullying, or explicit suggestion (Brown, 2008). Many studies have found that close friends and romantic peers influence adolescents' decisions to engage in romantic and sexual activity (Ali & Dwyer, 2011; Crockett, Rafaelli, Shen, 2006; Kennett, Humphreys, & Schultz, 2012). For example, in one study, negative peer pressure to engage in sexual activity was found to increase the likelihood that adolescents will engage in risky sexual behaviors, both directly and indirectly (through the increased use of substances) (Crockett et al., 2006). In an earlier review by the same authors, negative peer pressure was found to be a risk factor for early and risky sexual behaviors (Crockett, Rafaelli, Shen, 2003). Qualitative examinations have found similar results, with 60% of participants in one study reporting that they engaged in unwanted sexual activity as a result of pressure from their partners. In another study, gender differences were subtle, yet apparent, with females reporting that they were more likely to engage in sexual behaviors that contradicted their personal desires and needs in an effort to keep their partners happy and engaged (Suleiman & Deardorff, 2015).

In the study being reported in this chapter, similar gender differences were found (see *Results*, below), suggesting that peer pressure may play a larger role for females in adolescent

decisions about sexual behaviors. Unfortunately, though the link between peer pressure and adolescent sexual behaviors seems clear, there is little research examining the role of peer pressure in *digital* sexual behaviors.

Sexual Harassment

Traditional sexual harassment seems to be a common problem for teens (as individuals and as a group). A 1993 survey of 2,064 public school students, and a repeat of that study in 2001, found that over 80% of teens reported having been a target of sexual harassment (American Association of University Women Educational Foundation [AAUW], 1993). Other studies confirm these high numbers (Fineran & Bennett, 1999; Stein & Bogart, 1987). Physical sexual harassment (a more severe variety) was experienced at some time by 58% of students in the AAUW study. No matter the form it takes, sexual harassment is a serious public health threat; it has been linked to physical violence and profound psychological damage. A substantial amount of research, reaching back decades, has documented the association between sexual harassment and depression. Studies examining sexually harassed adults have found that victims experienced higher levels of depression, anxiety, and aggression (Bjorkqvist, Osterman, & Hjelt-Back, 1994; Ho, Dinh, Bellefontaine, & Irving, 2012; Humphreys & Lee, 2009). Among children and teens, those who reported the highest level of peer sexual harassment also showed the highest anxiety and depression levels (Espelage & Holt, 2007). Sexual harassment has been particularly associated with depression among students with a sexual minority status (Martin-Storey & Crosnoe, 2012).

Digital forms of sexual harassment (DSH) have also been studied but in comparison to sexual harassment in person, they can be more difficult to define precisely. For example, if an online stranger asks to meet someone in person, or asks for a photo, that could be construed as a sexual advance – or not, depending on the context in which the solicitation occurred. Unlike face to face encounters, in digital environments, the intention of the inviter can be hard to ascertain. Being sent a nude picture or a picture of people having sex is clearly sexual harassment - unless the recipient requested such images. Pictures of a nude peer may be shared with others, not for the purpose of harassing the recipient but instead to simply share an intensely interesting photo with a friend (Englander, 2012). Yet there are also some digital events that seem very likely to be sexual harassment, such as telling a peer that they won't be offered a date unless they provide a nude picture of themselves, or soliciting someone sexually online or through texting. Drawing a distinction between what is clearly DSH, and what might not be, is difficult.

A few studies have suggested that sexualized digital behaviors may be sexual harassment by finding links between such behaviors and emotional trauma, including depression (Mitchell, Ybarra, & Finkelhor, 2007) and stress symptoms (Wolak, Mitchell, & Finkelhor, 2006). Unfortunately, current research protocols do not always consider digital behaviors, and in other studies conducted at the Massachusetts Aggression Reduction Center in 2011 and 2012, 65% of teens reported that when adults were questioning them about peer harassment and bullying, no questions about digital behaviors were ever asked (Englander, 2013), in spite of the well-known predominance of digital communications between youth today.

PRESSURED OR COERCED SEXTING

This chapter reports on one wave of data collected as part of an ongoing study conducted by researchers at the Massachusetts Aggression Reduction Center at Bridgewater State University in Massachusetts. In this ongoing study, college freshman are confidentially surveyed about their experiences in high school with regards to bullying, cyberbullying, and digital behaviors. The data presented here will examine the relationship between sexting, pressured or coerced sexting, and psychological functioning. We asked subjects about pressure or coercion that happened directly (e.g., being pestered to send a nude picture), but we also asked about another possible source of sexual harassment that might occur after a photo is sent: the picture, even if sent willingly and in confidence to one person, might ultimately be distributed widely by that trusted recipient. Certainly distributing nude photos is not rare; two studies have both found that about 25% to 30% of those youth who receive nude photos subsequently forward the pictures to others (Englander, 2014; Strassberg, McKinnon, Sustaíta, & Rullo, 2013). However, this data does not speak to the intention of a distributor (e.g., to harm the sexter); adolescents are naturally inquisitive about nudity and sexuality and sharing nude photos (of others) certainly predates the Internet (Englander, 2012b).

RESULTS AND DISCUSSION

Overall, 27% of 18-year-old participants reported that they had sexted prior to age 18. The trend of sexting increased as they matured. More than half of sexters (56%) said that they had sexted during 11th grade, while “only” 27% reported sexting during 9th grade. Surprisingly, 17% said they had sexted prior to high school.

We proposed that being pressured and/or coerced into sexting would be a very rare occurrence, but overall, about half of the sexters reported that they felt pressured, coerced, blackmailed, bullied, or threatened into sexting (Englander, 2013).

This proportion was consistent with the waves of data collected in both 2011 and 2012 (Englander, 2012a). We are not the only researchers who picked up on this trend: a qualitative report released earlier this year in the United Kingdom also identified coercive sexting as a major area of concern (Ringrose, Gill, Livingstone, & Harvey, 2012).

Of the sexters, high proportions reported at least some peer pressure or more serious coercion, but not all such pressure was experienced negatively. Still, subjects who were pressured or coerced into sexting reported higher levels of emotional distress as a result of the sexting incident. When asked to rate, on a scale of 1 to 10, how upsetting it had been to send the nude picture, those who sexted voluntarily didn’t experience it as very upsetting. Most of them (79%) selected the “least upset” ratings (a 1 or 2 out of 10). But those subjects who were pressured and/or coerced into sexting felt much more upset by the experience.

In contrast to the willing sexters, only 17% of the pressured sexters selected the “least upset” rating. But not all chose the “most upset” rating, either; “only” about 36% of those who were pressured reported that it caused significant emotional distress, and many “distributed sexters” (i.e., those who knew their photo was distributed to others) reported feeling little or no regret or anguish about having sexted (Englander, 2014).

While clearly pressured and coerced sexting increases the likelihood of emotional trauma, these data suggest that we cannot assume that all pressured sexting, and all unauthorized distribution, *automatically* constitute harassment.

What Motivates Sexting?

Willing and pressured sexters did not only differ on how upset they felt about sexting, they also differed on their motivations for sexting. Both types were most likely to report that a boyfriend or girlfriend wanted the picture, and least likely to say that someone at school or online had blackmailed them into providing the picture. But pressured sexters were three times as likely (55% versus 18%) to say that a *prospective* date (i.e., someone they weren't yet dating, but wanted to) asked for the picture, and they were also more likely to report that they were uncomfortable about providing the picture but ultimately decided that it "wasn't a big deal." As for any negative consequences following the sexting, almost a third of pressured sexters reported problems with peers or adults after they sent the picture (32%), but only 8% of willing sexters had those problems.

Gender differences were apparent in the study, where we noted that girls were more likely than boys to report that they had sexted. Interestingly, this difference was entirely due to more girls reporting that they had been pressured, coerced, blackmailed, or threatened into sexting. The genders did not differ on rates of voluntary or willing sexting.

PRESSURED SEXTING AND RELATIONSHIP PROBLEMS

Pressured sexters also seem at risk for experiencing *some* types of prior violence in relationships, but they showed no elevated risk for other types. For example, pressured sexters were more likely to report that they experienced prior dating violence; almost half (48%) of pressured sexters indicated these experiences as compared to only one-third of non-pressured sexters and one-fourth of nonsexters. Conversely, pressured and non-pressured sexters were similarly elevated in levels of prior family violence. It appears that prior violence as a risk factor is limited to dating violence.

Although some teens do appear to worry about the impact of sexting on their relationships with peers, parents, and other adults at school, in reality that does not appear to be a highly likely consequence. This is probably because while the media does seem to focus on cases where photos are widely distributed, our data suggests that this is an outcome that is far from universal. In this present study, slightly fewer than three-quarters (73%) of all sexters reported that to their knowledge, the picture(s) was never shown to anyone apart from the intended recipient. Willing sexters were less likely to say the picture was "passed around" (15% reported this), but even among pressured sexters, passing around wasn't overwhelmingly common, with "only" slightly more than a third reporting that the nude self-portrait was shown to others (34%). It is clear that in some instances nude self-portraits are passed around, but even those cases do not inevitably constitute episodes in which these pictures are seen by many others, as is often implied in the media. Our data suggests that overall, 19% of sexters reported that the picture was seen by one or two people after the original recipient, and only 8% said it was seen

by three or more. Even when the picture was disseminated, it didn't always lead to trouble - although 27% of sexters reported that others saw their nude picture, only 18% said it caused trouble for them. Notably, when these images *are* seen by others, and then do cause problems, it does not seem to be the adults who generally see and respond to them. Sexters reported that their parents saw the image only 3% to 4% of the time, and both pressured and willing sexters reported getting into trouble with their parents because of the picture at very low rates (only 5.4% and 3%, respectively). Rates of getting into trouble with the adults at school were even lower - about 1% and 3%, respectively.

In contrast, trouble from peers was the most common type, for both pressured and willing sexters. About 14% of pressured sexters and 6% of willing sexters reported having trouble from peers because of the pictures that were shown around. We did not ask subjects about specific types of problems with peers, but anecdotal conversations with teens whom we encounter in the schools in which we work suggests that these problems may cluster around gossip and rumors, sexual harassment, and in more severe cases, social rejection and/or extreme humiliation and isolation. Our experience leads us to believe that the social impact of sexting, if taken to extremes by peers, can be potentially devastating. Luckily, such outcomes seem to be the exception, rather than the rule.

Raising a Red Flag on Coerced Sexting

Although our findings reveal that sexting is less likely to result in a backlash than the media might have led us to believe, the fact that teens may sext when coerced or pressured to do so is a problem that should not be minimized. As noted above, about half of the girls and a third of the boys who sexted said they did so at least once because someone else pressured or coerced them to send a nude picture. Pressure applied in the context of a relationship (i.e., with a current boyfriend or girlfriend) wasn't always experienced as a problem; what's of more concern are the subjects who did experience the pressure negatively, most commonly when the pressure came from someone the sexter wanted to date (most often a potential boyfriend). It is troubling to think that intimate pictures might be solicited from vulnerable, eager-to-please teenagers. Although we do not by any means think the higher rates of depression and substance abuse among all types of sexters should be ignored, the pressured sexters seem to be dealing with an additional set of troubles. They were the sexters most likely to have a history of dating violence and most likely to report that the picture(s) ultimately caused problems for them, usually with their peers and occasionally with adults. Thus, they may be the most vulnerable students - prior victims who are being re-victimized.

Future research could help further our understanding of digital forms of sexual harassment. This current study was limited by its design (college freshman retrospectively recalling their behavior during high school) and by the nature of the variables studied. It is likely that the relationship between sexters and recipients may be far more nuanced and complex; for example, the role of friends, peers, and family needs to be explored to understand how digital sexual harassment occurs and what its consequences may be. This study has made it clear, however, that ignoring digital forms of harassment is likely to omit important sources of social stress and conflict between youth.

Chapter 8

THE ROLE OF EMOTIONAL PROCESSES IN (CYBER)BULLYING

Enrica Ciucci* and Andrea Baroncelli

University of Florence

INTRODUCTION

In a recent meta-analysis by Cook, Williams, Guerra, Kim, and Sadek (2010) on bullying and victimization in childhood and adolescence, they stressed that the most investigated predictors of both phenomena are individual characteristics, mainly gender, externalizing and internalizing behaviors, academic performance, self-related cognitions, other-related cognitions, and social problem-solving. However, among the individual-level predictors, scarce consideration was given to the role of emotions (e.g., individual traits, temperamental characteristics, abilities). This evidence is particularly pronounced in the field of research on cyberbullying, because of the lack of face-to-face interaction. The main aim of the present chapter is to review recent literature about bullying and cyberbullying in order to make an in-depth exploration of the role of emotional processes in these maladaptive behaviors. In line with the general aim of the present book, we will use the terms “bullying,” “traditional bullying,” or “face-to-face bullying” to refer to a maladaptive relationship in which individuals (or groups of individuals) repeatedly and intentionally harass those unable to defend themselves through physical, verbal, or relational (i.e., covert) behaviors (Olweus, 1993; Salmivalli, 2010). We will use the labels “cyberbullying,” “electronic bullying,” or “new forms of bullying” to refer to bullying behaviors characterized by offensive acts (e.g., harassment, cyberstalking, spreading of rumors, intimidation, etc.) inflicted through new technological means, such as social networking sites, instant messaging, blogs, and chat rooms (Menesini, Calussi, & Nocentini, 2012; Palladino, Nocentini, & Menesini, 2015; Williams & Guerra, 2007). A continuous effort will be made in order to trace similarities and differences between traditional and new forms of bullying in association with emotional processes, and research from face-to-face bullying will be used to provide a starting point in order to understand bullying in

* Corresponding Author’s Email: enrica.ciucci@unifi.it

cyberspace. Given the overlap between traditional and cyberbullying phenomena (Juvonen & Gross, 2008; Raskauskas & Stoltz, 2007; Wang, Iannotti, & Luk, 2012), we agree with Dooley, Pyzalski, and Cross (2009) that it is necessary to identify the unique emotional characteristics of individuals who exclusively engage in electronic bullying, in order to account for specific risk factors that play a role in predicting this new form of bullying.

As far as traditional bullying is concerned, the Social Information Processing Model (SIP) and the Theory of Mind Approach (TOM) as applied to children's aggressive behaviors (Arsenio & Lemerise, 2001; Sutton, Smith, & Swettenham, 2001) put little emphasis on the role played by emotions in bullying behaviors. According to the SIP model (Crick & Dodge, 1994, 1999), biases or deficits in one or more of the six steps in processing social information (i.e., encoding both internal and external cues, interpretations of cues, clarification of goals, response access and construction, response decision, and behavior enactment) were seen as leading to aggressive behavior in a child. Like aggressive children, bullies were hypothesized to have problems in the initial stages of processing (i.e., encoding and interpretation of social cues), but the empirical data did not confirm this assumption: many bullies were able to accurately perceive their social world and they had more advanced theory of mind skills (i.e., the ability to recognize others' emotions, intentions, beliefs, and goals). Instead, they displayed a "biased" response evaluation style and were more prone to choose self-oriented goals (e.g., material goals, social visibility, and/or a powerful position within the peer group), without experiencing aversive vicarious emotions due to the consequences of their actions on the victim (Sutton, Smith, & Swettenham, 1999a, 1999b, 2001). A different picture of the nature of bullying emerged: bullies were considered skilled and strategic manipulators who were able to latch onto victims' vulnerability and manipulate the social context by displaying "cold cognition," that is, a theory of mind formulated in instrumental terms without access to the empathic understanding of others (Sutton et al., 1999b). The involvement of TOM skills in bullying behavior goes hand in hand with the revision of the SIP model, by taking systematic account of the role of emotions and emotional processes in understanding social behavior. Specifically, the revised SIP model by Lemerise and Arsenio (2000) hypothesized that emotionality and regulatory ability strictly affects all steps of social information processing during interpersonal interactions.

Despite the theoretical recognition of the contribution of emotion processes to bullying phenomena, this topic has received scarce empirical support. In the present chapter, we will review some studies investigating the role of emotions in (cyber)bullying, while focusing our attention on specific topics concerning both traditional and current fields of research. First, we will focus on the role of emotion perception abilities, which represent the first step of the SIP model, and then we will consider the effect of emotionality and the emotion regulation processes that can affect what emotion cues are noticed and how they are interpreted. This section will conclude with some studies on the happy victimizer paradigm, which investigate how bullies and victims attribute emotions to hypothetical moral transgressors, and, indirectly, to hypothetical victims. We consider this a very promising area of study on cyberbullying yet to be explored, since in cyberspace the victims' emotional contingent reaction is lacking and bullies can only consider the victims' expected emotions in order to evaluate the effectiveness of their harassment. Second, we consider studies on empathy and callous-unemotional traits in order to explore (cyber)bullies' subjective dispositions in relation to others' emotions. Finally, we will review some studies on emotional intelligence that try to explore whether (cyber)bullies perceive themselves as able to handle both their own and others' emotions.

From a life-span developmental perspective, we emphasize the importance of age-related changes in the emotional correlates of (cyber)bullying behaviors. Nevertheless, we particularly focus on preadolescence and middle school (grades 6 to 8); preadolescence represents the transition from late childhood into adolescence, and it constitutes a period of rapid biological, psychological, and relational changes, having strong implications for future development trajectories; moreover, past research has indicated that bullying peaks during preadolescence, and cyberbullying is mainly committed by preadolescents and adolescents who are increasingly using new technologies (Brown, Birch, & Kancherla, 2005; Fitzpatrick, Dulin, & Piko, 2007; Hinduja & Patchin, 2008; Smith, Mahdavi, Carvalho, Fisher, Russel, & Tippett, 2008).

WHEN (CYBER)BULLIES MEET OTHERS: THE ROLE OF EMOTION PERCEPTION ABILITIES, EMOTIONALITY AND EMOTION REGULATION

The first step of both the original and revised SIP model involves the ability to encode social cues (Crick & Dodge, 1994, 1999; Lemerise & Arsenio, 2000). Among the social abilities, emotion perception is considered a basic nonverbal skill comprising two distinct albeit associated processes: emotion perception accuracy (i.e., the ability to perceive a discrete emotion when it is actually expressed; for instance, children who are highly accurate at perceiving happiness tend to correctly identify or label happiness emotions when actual cues are expressed) and emotion perception bias (i.e., the tendency to perceive a discrete emotion when a different emotion is expressed; for instance, children with high levels of bias in perceiving happiness tend to mistakenly identify or label non-happy emotions as happiness). Izard and collaborators (Ackerman, Abe, & Izard, 1998; Izard, 1977, 2002) emphasized that emotion perception bias results from increased exposure to a particular emotion in others or increased emotional arousal experienced in themselves.

Children who are accurate at identifying others' verbal and nonverbal emotional cues are more likely to experience positive interactions with peers than those who are less accurate in this domain (Goodfellow & Nowicki, 2009; Mostow, Izard, Fine, & Trentacosta, 2002). In addition, the damaging role of emotion perception bias in social information processing has been outlined in several studies. In particular, research on socially rejected and aggressive children has revealed that these children are more likely to inaccurately recognize their peers' expressions of emotion and systematically attribute anger in ambiguous situations (Crick & Dodge, 1994; Orobio de Castro, Merk, Koops, Veerman, & Bosch, 2005; Schultz, Izard, & Ackerman, 2000). In other words, specific emotion perception bias interferes with children's ability to accurately collect and use the available emotional information, which in turn negatively influences the subsequent steps in social information processing (Barth & Bastiani, 1997; Rosen, Milich, & Harris, 2007). Furthermore, when emotion perception accuracy and emotion perception bias were simultaneously evaluated, it was found that recognition biases often played a more significant role in predicting social behavior than recognition accuracy (Barth & Bastiani, 1997; Fine, Trentacosta, Izard, Mostow, & Campbell, 2004; Schultz, Izard, & Ackerman, 2000).

What do we know about (cyber)bullying and emotion perception abilities? Studies on traditional bullying (Ciucci & Fonzi, 1999; Woods, Wolke, Nowicki, & Hall, 2009) have found

that bullies do not differ from peers in their overall accuracy when reading emotions in others' faces. We argue here that the ability to "see" victims' vulnerability (e.g., emotional cues of distress and anger) as communicated through their nonverbal and verbal social responses is fundamental because it acts as an immediate and tangible reinforcement to bullies' desire to dominate others (Pepler, Jiang, Craig, & Connolly, 2008; Perry, Williard, & Perry, 1990; Vandebosch & van Cleemput, 2008). Conversely, it was found that victims (especially relational victims) made more errors in perceiving expressions of anger and fear compared to non-involved peers (Woods et al., 2009); in addition, victims were more prone to "preemptively" process threatening social stimuli, thus impairing their ability to decode threat due to their dysregulated negative emotional arousal (Rosen et al., 2007).

As for cyberbullying, it is reasonable to expect that the association with emotion perception accuracy may be different, considering that cyberbullies are often removed from face-to-face interaction. They do not always have the opportunity to view the emotional impact of their actions on victims. Rather, they can have expectations about the emotional consequences of their behaviors which may motivate their response evaluation process (Dooley et al., 2009; Ybarra & Mitchell, 2004).

To date, only one study (Ciucci, Baroncelli, & Nowicki, 2014) has conjunctly investigated the possible associations between face-to-face and cyber forms of bullying and victimization behavior, with both perception accuracy and perception bias in a sample of middle school preadolescents. In addition, this study paid particular attention to measuring the unique associations of each of the bullying scales (e.g., traditional bullying) with emotion perception processes, while controlling for the other three bullying scales (e.g., cyberbullying, traditional victimization, and cyber victimization) and emotionality. In so doing, the authors aimed to control the co-occurrence of bullying phenomena as well as the level of personal arousal. The results suggested that emotion perception abilities are important in bullying and victimization interactions for boys but not for girls; specifically, the results revealed that males who were more inclined toward traditional bullying did not show any deficit in accurately perceiving emotions, while they were more prone to over-perceive happiness and fear in the absence of actual cues. Both these perception biases may serve to reinforce bullies' behaviors and perpetuate the cycle of victimization: a bias in perceiving happiness may encourage bullies to interact with peers (including victims) because they perceive signs of pleasure or approval in others' faces; moreover, bullies could perceive displays of fear in others' facial expressions as a sign of their social dominance. Importantly, males who were more inclined toward cyberbullying could perceive fear more accurately, which may suggest the possibility that they use this information to select their victims; nevertheless, it remains unclear why the accurate recognition of this emotion is more important in cyberbullying rather than the traditional form of bullying. We could hypothesize that in face-to-face bullying, both in bullies (probably anger and joy) and in victims (fear), the role of emotional arousal is preeminent in determining over-perception of the victims' fear. The ability to accurately identify fear in victims could facilitate repeated and systematic offline abuse, but its preferential use in online interactions could be explained by its co-occurrence with social anxiety (high level of fear arousal), determining cyberbullies' preference to hide themselves behind a technological medium. This hypothesis derives from research supporting evidence of an association between problematic Internet use and shyness, loneliness, and avoiding social relationships (Ceyhan & Ceyhan, 2008; Gross, Juvonen, & Gable, 2002; Hardie & Yi-Tee, 2007). Further research that explicitly considered

the interactive effects of emotional perception processes, emotionality, and social involvement in association with cyberbullying needs to be performed to better understand extant results.

Conversely, Ciucci, Baroncelli, and Nowicki (2014) found that male cyber victims showed deficiency in emotion perception processes: they conjunctly revealed less accuracy in perceiving emotions, especially anger and fear, and a greater bias perception of anger and fear when other emotions were displayed. Considering these important deficits, male cyber victims find it difficult to assess whether others are potentially dangerous, or whether others are signaling that there is a threat in the situation. This tendency to mix anger and fear magnifies the potential of these nonverbal errors, heightening the risk of being bullied.

As already stated, the ability to accurately read others' emotional signals is strictly related to the quality of one's own emotional experiences. Studies on bullies and victims' emotionality may be relevant to this investigation. The intensity of the experienced emotions along with the scarce capacity to regulate them (i.e., proneness to anger, emotional lability/negativity, and low levels of fear reactivity and effortful control) are two emotional processes that influence bullying behaviors, even if bullies appear as skilled as other peers in their knowledge of emotional display rules (Camodeca & Goossens, 2005; Espelage, Bosworth, & Simon, 2001; Garner & Hinton, 2010; Terranova, Sheffield Morris, & Boxer, 2008). Bullies and victims' emotionality could be important because the emotional arousal they experience could serve to strengthen their affective-cognitive structures related to a discrete emotion (Ackerman et al., 1998; Izard, 1977, 2002; Rosen et al., 2007). For instance, Camodeca and Goossens (2005) found that bullies and victims react similarly to hypothetical SIP situations with anger, while victims also react with sadness. By directly observing emotional display and emotional regulation in classroom bullying episodes, Mahady Wilton, Craig, and Pepler (2000) found that interest, joy, and anger were not only the most frequently observed emotional displays among bullies, but also among victims, with maladaptive consequences. In addition, Mahady Wilton et al. (2000) found that bullies expressed joy and anger more easily than victims; in contrast, victims were more prone to express surprise and sadness than bullies. When talking about their victimization, the victims told stories full of negative emotions, involving both distress caused by the victimization episodes and anger toward their perpetrators. During bullying episodes, bullies reported feeling better and less guilty for their victims compared to peers who were less involved in bullying behaviors (Bollmer, Harris, & Milich, 2006). Once again, the extant research mainly focuses on traditional bullying, while the few studies on this topic in relation to cyber phenomena have found that the typical emotions aroused in cyber victims included frustration, anger, sadness, and fear (Beran & Li, 2005; Hynduia & Patchin, 2007; Patchin & Hynduia, 2006; Spears, Slee, Owens, & Johnson, 2009). Further research on the role of emotionality in cyberbullying, as well as studies on the pre-emptive processing of emotional information, is necessary.

Prior to concluding this section, we want to report the findings of an interesting field of research that adopted the happy victimizer paradigm, a task developed in order to study the emotions that children attributed to a moral victimizer when confronted with hypothetical situations of moral violation. The results suggested that more often aggressive children attributed happiness to the perpetrators of moral infractions that produce personal gains, indicating that the former lack moral motivation (Arsenio, Gold, & Adams, 2006; Malti & Krettenauer, 2013). Other studies confirmed that bullies attributed positive emotions to a hypothetical moral transgressor more often and moral emotion attributions such as sadness and feelings of guilt less often (Gasser & Keller, 2010; Menesini, Sanchez, Fonzi, Ortega,

Costabile, & Lo Feudo, 2003). Similarly, in the face of real incidents of bullying, bullies were much more likely to say that they felt happy about the episode and much less likely to say that the victims felt unhappy than the victims or control peers (Smith, Bowers, Binney, & Cowie, 1993). Although to date no study has included electronic forms of bullying, we consider the happy victimizer paradigm particularly promising in cyberbullying research: considering that cyberbullies are removed from face-to-face interactions with their victims, it is crucial to assess how they expect to feel following the harassment, as well as how they expect their victims to feel and react as a result of their aggressive behaviors.

(CYBER)BULLIES' SUBJECTIVE DISPOSITIONS IN RELATION TO OTHERS' EMOTIONS: THE ROLE OF EMPATHY AND CALLOUS-UNEMOTIONAL TRAITS

A large amount of research has examined the individual factors that contribute to making a child more prone to harass others: it has been found that proactively aggressive individuals, such as bullies, are more likely to be characterized by a lack of empathy. Empathy can be defined as a multidimensional construct, involving a cognitive dimension that refers to the ability to recognize others' feelings, and an affective dimension that refers to the ability to share the affective state of others (Davis, 1983; Feshbach & Feshbach, 1982). Several studies have highlighted that the affective component of empathy could be the main emotional deficiency in traditional bullying, and especially in male bullies (Caravita, Di Blasio, & Salmivalli 2009; Jolliffe & Farrington, 2006, 2011; Stavrinides, Georgiou, & Theofanous, 2010). As regards the relationship between empathy and different forms of traditional bullying, Jolliffe and Farrington (2006) found that physical bullying was negatively associated with general empathy among adolescent males, whereas indirect bullying was negatively related to affective and total empathy among adolescent females. In a subsequent study, Jolliffe and Farrington (2011) showed that affective empathy was negatively associated with both physical and verbal forms for males, while female bullying was not related to either cognitive or affective empathy. Considering cyberbullying, the results are as inconsistent as in the traditional form: Almeida, Marinho, Esteves, Gomes, and Correia (2008) found that cyberbullies do not show a lack of empathy while Steffgen, Pfetsch, König, and Melzer (2011) revealed that cyberbullies were less empathic than peers. Renati, Berrone, Fedrigi, and Zanetti (2011) found a negative relation between affective empathy and cyberbullying. Ang and Goh (2010) provided an interesting study in which the unique and interactive effects of both affective and cognitive empathy were tested in association with cyberbullying: the results showed that in male adolescents' higher levels of cyberbullying were associated with lower levels of cognitive empathy over and above the role of affective empathy; in female adolescents the same association was only found in those with low affective empathy but not in those with high affective empathy. This was interpreted on the basis of Silfver and Helkama's results (2007) that moral decision-making in boys is based more on cognitive components of empathy than in girls. We may assume that in boys the electronic medium serves to deal with a weak theory of mind and, therefore, a lower premeditated planning capacity; in contrast, females may only resort to electronic media as well as indirect bullying when they have not vicariously

experienced others' emotions. In summary, the role of empathy in traditional bullying and cyberbullying still needs more investigation, especially in relation to gender.

Empathy, and especially affective empathy, is a construct that is strictly related to Callous-Unemotional traits (CU). In the Fifth Edition of the Diagnostic and Statistical Manual for Mental Disorders (DSM-5), the diagnostic criteria for Conduct Disorder (CD) were extended to include a specifier designating important subgroups of children and adolescents "with Limited Prosocial Emotions." Specifically, these children are characterized by uncaring (i.e., lack of remorse or guilt, lack of concern about performance in important activities), callousness (i.e., callous-lack of empathy), and unemotional (i.e., shallow or deficient affect) dimensions (Frick & Nigg, 2012). Children and adolescents with behavior problems who also show high levels of CU traits exhibit more severe and chronic antisocial behaviors than those with normative CU trait levels (Kahn, Frick, Youngstrom, Findling, & Youngstrom, 2012), and that they are resistant to traditional treatments (Frick & White, 2008). Moreover, children and adolescents with behavior problems who also exhibit a high level of CU traits show a number of unique genetic, neurological, cognitive, emotional, personality, and social characteristics (Frick, Ray, Thornton, & Kahn, 2014) which could suggest that children and adolescents with these traits have different causal factors leading to their behavior problems compared to other antisocial youths.

A current field of research has identified CU traits as a critical construct for an in-depth exploration of the etiology of bullying behaviors. For instance, higher levels of CU traits were related positively to direct bullying in British preadolescents (Viding, Simmonds, Petrides, & Frederickson, 2009) and to bullying behaviors in American preadolescent girls with conduct disorder symptoms (Pardini, Stepp, Hipwell, Stouthamer-Loeber, & Loeber, 2012). Other studies examined the role of different dimensions of CU traits (i.e., callousness, uncaring, and unemotional) in bullying. In preadolescent and adolescent Greek Cypriot students, Fanti, Frick, and Georgiou (2009) found that those who exhibited pure bullying scored higher on the uncaring dimension when compared to those exhibiting low bullying, pure victimization, or a combination of bullying and victimization. Ciucci, Baroncelli, Franchi, Golmaryami, and Frick (2014) explored the unique variance accounted for both bullying and cyberbullying by the three CU dimensions and found that in boys callousness and an uncaring attitude contributed uniquely to the prediction of face-to-face bullying, while an uncaring attitude alone was uniquely associated with cyberbullying. On the other hand, in girls the uncaring dimension was the only one associated with both offline and online bullying behaviors. The uncaring dimension, which includes a lack of care about one's performance in tasks as well as a lack of care about others' emotions, seems to be more strongly associated with both bullying phenomena. It is interesting to notice that, among the other CU dimensions, this dimension of disregard for others seems to be more strongly related to measures of severe delinquent behaviors in detained or incarcerated juveniles (Kimonis et al., 2008).

As we previously stated, there is no doubt that the callous CU trait overlaps with the construct of affective empathy, and some interesting studies further explore the unique role played by empathy and CU trait dimensions in their association with bullying. A recent contribution by Muñoz, Qualter, and Padgett (2011) found that both cognitive and affective empathy were associated with bullying in preadolescents, but these associations did not emerge when the personality trait related to not caring about others (i.e., the uncaring CU trait) was taken into account. The authors concluded that CU traits were more important than empathic disposition in predicting bullying behaviors. Following the results of Muñoz and colleagues

(2011), Ciucci and Baroncelli (2014a) tried to address some of the limitations of previous studies and aimed to determine which specific dimensions of empathy and CU traits were uniquely associated with bullying in preadolescence, while controlling for the level of victimization. Moreover, they attempted to highlight possible age-related effects. Their results indicated that for preadolescents in 6th grade the uncaring CU trait was positively related to bullying, but this association was mediated by a lack of the affective component of empathy; as for preadolescents in 8th grade the callous CU trait was directly related to bullying, while empathy proved not to be associated when CU traits were considered. The authors concluded that a callous attitude had a greater impact on determining bullying behaviors in older preadolescents than in younger ones, probably because these traits become more stable and solidified in the personality of near adolescents, as stated by Pardini and colleagues (2012).

Considering the role of CU traits in cyberbullying, a recent study on middle school students conducted by Ciucci and Baroncelli (2014b) revealed some interesting findings. In this study, the authors aimed to investigate the dynamic relationship between children's individual characteristics (i.e., CU traits) and the experienced social context (i.e., social preference and perceived popularity) on cyberbullying behaviors, while controlling for cyber victimization. In girls, higher levels of cyberbullying were associated with a more uncaring disposition towards others, but this effect was not influenced by interaction terms with social preference or perceived popularity. Conversely, boys with a more uncaring attitude were more likely to be involved in cyberbullying behaviors when combined with lower levels of social visibility and prestige within the peer group: this result indicated that the uncaring CU trait represents an individual risk factor that is maximized by disadvantaged social circumstances. Further research is needed to make an in-depth exploration of why this interactive effect is only significant in boys; the authors have put forward the hypothesis that in children approaching adolescence the strain for social status is more important for males than for girls: while preadolescent females are more likely to be involved in close dyadic relationships, such as love stories and friendships, boys are more likely to be building their social reputation and visibility within the broader peer group (Benenson, 1990; Sitsema, Veenstra, Lindenberg, & Salmivalli, 2009). To summarize, recent research on emotions and both bullying and cyberbullying has shown the importance of making an in-depth exploration of the emotional profiles of the boys and girls involved in these maladaptive behaviors; this will clearly trace whether the traditional field of research on bullies' empathy can be integrated with the more recent field of emotion-related personality traits.

HANDLING OWN AND OTHERS' EMOTIONS: THE ROLE OF (CYBER)BULLIES' EMOTIONAL INTELLIGENCE

The above-mentioned studies on the perceptual and individual emotion-related characteristics that could be involved in (cyber)bullying lead us wonder how (cyber)bullies are able to handle their own and others' emotions, and how they perceive this. In other words, we cannot conclude this chapter without focusing on (cyber)bullies' emotional intelligence. Emotional Intelligence (EI) was described by Salovey & Mayer (1990, p.189) as *"the subset of social intelligence that involves the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and*

actions.” According to this model, EI is a cognitive ability that is orthogonal to other intelligences; during time, different definitions have been put forward of EI, including broader non-cognitive aspects, such as competencies, skills and personality traits (Bar-On, 1997; Goleman, 1995; Petrides & Furnham, 2001). This trend brings EI close to another similar construct: emotional competence (Denham, 1998; Saarni, 1999). Denham, Zinsler, and Bailey (2011) use these two terms interchangeably, identifying three constituent dimensions: knowledge, expression, and regulation of own and others’ emotions.

To date, the role of EI in relation to bullying has received scarce attention; Mavroveli and Sánchez-Ruiz (2011) found a negative association between a total score of EI and both self-reported and peer-reported bullying in a sample of English primary school students. Kokkinos and Kipritsi (2012) observed that a total score of trait EI was negatively associated with both direct and indirect forms of bullying in Greek primary school students. Considering the subcomponents of trait EI, Lomas, Stough, Hansen, and Downey (2012) found that the self-perceived understanding of others’ emotions was negatively associated with bullying in a small sample of Australian preadolescents, suggesting that students who felt impaired in understanding others’ emotions were also unable to understand the consequences of their harassment behaviors; nevertheless, the low number of participants suggests caution in generalizing the results. The above-mentioned studies are crucial in that they investigated how self-beliefs about own emotional skills are associated with bullying; nevertheless, they did not simultaneously consider different forms of bullying (i.e., traditional bullying and cyberbullying) in association with different dimensions of EI (i.e., emotional appraisal, use and regulation of both own and others’ emotions). A recent study by Baroncelli and Ciucci (2014) tried to fill this gap, by investigating the associations of discrete trait EI dimensions with traditional bullying and cyberbullying, over and above involvement in other forms of bullying/victimization. The results of this study showed that the dimension of EI concerning the regulation and use of emotions was negatively associated both with traditional bullying and cyberbullying. However, this association did not emerge when traditional bullying was controlled for cyberbullying, whilst it still emerged when cyberbullying was controlled for traditional bullying and both forms of victimization. Differently, dimensions concerning appraisal of own and others’ emotions were not associated with children’s bullying or cyberbullying behaviors. In summary, preadolescents with higher levels of bullying or cyberbullying did not perceive themselves as unable to detect emotional cues in the self or in others (i.e., the basic processes of emotional intelligence; Schutte et al., 1998). Rather, they perceived themselves as less able to regulate and use these emotions (i.e., the more evolved and integrated emotional intelligence processes). However, the latter evidence did not emerge in traditional bullying when it was controlled for cyberbullying. Baroncelli and Ciucci (2014) commented that criteria defining bullying behavior (i.e., intentionality, repetition over time, cold cognition) suggest that bullies may not have an impaired emotional functioning, and may be aware of this. This awareness, which could derive from mastery experiences, may empower the motivation to accurately identify victims’ body language and facial expression in order to carry out the harassment; moreover, it could promote the monitoring of peers’ reactions to gain a dominant role within the class group (Salmivalli, 2010). In addition, they did not consider themselves deficient in accurately monitoring and regulating their emotional states. Indeed, this may result effective while they perform bullying behaviors, in terms of choosing the best way of harassing victims without incurring sanctions. Similarly, cyberbullies did not perceive themselves as impaired in their basic emotional processes; once again, we can argue that self-

evaluation about these abilities may support them in acting out their cyberbullying behaviors. As largely highlighted in the previous section, cyberbullies are removed from face-to-face interactions with their victims and have to plan how to hurt them at a distance; in so doing, they may have to anticipate their victims' emotional reactions, while only relying on their own reactions to their acts (i.e., excitement) and sense of expectation. The main difference between the two forms of bullying concerns the self-perception of being able to use and regulate emotions: a lower level in this EI dimension was a significant predictor for cyberbullying, but not for traditional bullying. The ability to regulate and use emotion, but also the level of self-efficacy in this, has a core role in the SIP model (Lemerise & Arsenio, 2000). Saarni (1999) proved that children who are deficient in emotional regulation are less likely to consider multiple perspectives and more prone to choose a socially incompetent behavior. In addition, it can be hypothesized that poor regulators who are aware of their limits may intentionally choose an alternative option if they want to harass peers, and they may find it easier to bully in cyberspace rather than in face-to-face settings.

CONCLUSION

Research on the role of emotion processes in both (cyber)bullying and (cyber)victimization is timely. While rather limited, it is nevertheless fruitful (Camodeca & Goossens, 2005; Rosen et al., 2007; Woods et al., 2009). Considering this argument, most of the existing research has investigated traditional bullying and it is only recently that it has begun to examine the emotional characteristics of the individuals at risk of cyberbullying or cyber victimization (Ang & Goh, 2010; Ciucci & Baroncelli, 2014; Ciucci, Baroncelli, & Nowicki, 2014; Spears et al., 2009). Much of the recent interest in cyberspace is based on the belief that this form of bullying may exhibit unique characteristics compared to the off-line form, considering that cyberbullies and cyber victims are mainly removed from face-to-face interactions. A related consequence is that cyberbullies do not have direct feedback about the others' emotional reactions; thus, we have to assess how they expect to feel and how they expect their victims to feel following their cyber aggression.

The studies that have been considered in the present review - which does not claim to be complete or comprehensive - seemed important in order to point out some concluding remarks. The male students that were more prone to cyberbullying appeared more able to recognize the fear of others, even if they perceived themselves as less able to regulate their emotions. We have hypothesized that cyberbullies strategically put an electronic medium between themselves and their victims in order to cope with their perceived inability to regulate emotion during face-to-face social interactions: when a bully cannot face the others' suffering, it is more effective to switch to cyberspace. This can be read as a sign of great control and planning, but also as a sign of greater insecurity compared to traditional bullies. In this regard, it is important to note that, for cyberbullies, an uncaring disposition is preminent in order to harass peers in cyberspace; on the contrary, higher levels of the callous CU trait (which refers to lack of empathy and guilt) are fundamental in traditional bullying, where the physical presence of the other imposes a greater coldness in order to perform the aggression.

Our review has revealed only one paper that jointly examines the role of emotional individual characteristics and contextual factors in cyberbullying research. Specifically, Ciucci

and Baroncelli (2014b) found that male preadolescents with an uncaring disposition toward others' emotions and with low levels of popularity in the peer group are more likely to act out cyberbullying behaviors, maybe in order to gain visibility and prestige. According to a social-ecological approach, we hope that future research will consider the role of emotional processes in interaction with further contexts that play a central role in children's social competence, such as parent- and teacher-child relationships.

To conclude, we have to remark that, similarly to traditional bullying, gender seems to play a great role in cyberbullying too; from the role of the emotion perception processes, up to the impact of contextual factors in accentuating or decreasing the association between emotional characteristics and aggressive behaviors through electronic means, more research is needed to better identify the etiological processes that lead boys and girls to implement cyberbullying behaviors.

Chapter 9

WHO IS WHO IN CYBERBULLYING? CONCEPTUAL AND EMPIRICAL PERSPECTIVES ON BYSTANDERS IN CYBERBULLYING

Jan Pfetsch*, PhD

Technische Universität Berlin, Berlin, Germany

INTRODUCTION

Many cases of cyberbullying take place in the presence of others (e.g., sending degrading phone calls in a peer group), and some forms involve bystanders further perpetrating cyberbullying by causing additional harm to victims (e.g., spreading rumors in chat rooms or passing on embarrassing photos or videos via internet or mobile phones). While definitional aspects of traditional bullying include an intention to harm, a repetition of the act, and a power imbalance between bully and victim, the concept of cyberbullying is characterized through the use of technology to mediate the harmful communication (Tokunaga 2010). Two differences of cyberbullying in contrast from traditional bullying merit special attention: the wide audience and the complex roles of bystanders. Regarding the first aspect, cyberbullying differs from traditional bullying such that cyberbullying acts may reach a wide audience. In traditional bullying, only those who are physically present may witness the bullying act, in cyberbullying the text, photos, or videos may spread and be forwarded to a large audience. Cybervictims are often unsure about how many people have seen the degrading material and fear to lose social reputation. Concerning the second aspect, the bystander roles are more complex than in traditional bullying, because in traditional bullying bystanders are present offline only. In contrast, bystanders in cyberbullying may be present offline with the perpetrator when a harmful act is performed, offline with the victim when the message is received, or witnessing the incident directly while being online. Taking these two characteristics of the wide audience and bystander roles into account, the bystanding audience seems relevant for understanding the dynamics of the process of cyberbullying. But how do bystanders perceive cyberbullying

* Corresponding Author's Email: jan.pfetsch@tu-berlin.de.

incidents and how do the bystanders react to these experiences? While we have theoretical approaches to conceptualize the behavior and social role of bystanders in traditional bullying, this is an unclear point in cyberbullying. The current chapter focuses on the concept of bystanders in traditional bullying and cyberbullying from a theoretical perspective integrating existing empirical results in this area. A closer look at the social context of cyberbullying and the role that bystanders play for this behavior seems worthwhile for theoretical as well as for practical fields.

The current chapter refers to a socio-ecological model of bullying, acknowledging the social context of aggression and bullying on different levels (Espelage & Swearer 2003; Rodkin & Hodges 2003; Swearer, Espelage, Siebecker, Kingsbury & Bevins 2006). Bronfenbrenner (1979) suggested in his ecological theory that human development is nested in multiple environments—*micosystem*, *mesosystem*, *exosystem*, *makrosystem*, *chronosystem*—which are interrelated with each other and interactively influence human experiences, behavior, and development. Socio-ecological theory builds on this theoretical approach and suggests that “bullying and victimization are phenomena that are reciprocally influenced by the individual, family, school, peer group, community, and society” (Swearer et al., 2006, p. 257). Taking this perspective into account, the current contribution on bystanders in cyberbullying refers to the reciprocal influences of individual factors and peer group factors of the model, embedded in a digital communication environment. First, special characteristics of cyberbullying and bystanders in cyberbullying in contrast to traditional bullying are considered, then conceptual models of traditional bystanding are introduced which are of relevance for cyberbullying too. In the main part, existing empirical research about determinants and correlates of cyberbystanding behavior is reviewed. Building on this, a conceptual framework for cyberbystanding behavior is proposed and the chapter closes with hints on achieved milestones and future directions in the research on cyberbystanders.

CYBERBULLYING AND TRADITIONAL BULLYING

Traditional bullying is defined as a repeated, intentional act to harm another person including a power differential between a powerful individual or group of individuals of perpetrators and a powerless person being victimized (Olweus 1993). Cyberbullying is “any behavior performed through electronic or digital media by individuals or groups that repeatedly communicates hostile or aggressive messages intended to inflict harm or discomfort on others” (Tokunaga 2010, p. 278). Cyberbullying differs from traditional bullying in various aspects as it: (a) is conducted via technological devices, (b) is rather indirect, (c) does not provide direct feedback for the perpetrator about victim’s reactions, (d) leads to more complex bystander roles, (e) does not include direct status gain in front of witnesses, (f) has a larger potential audience, and (g) reaches victims wherever they are and is therefore difficult to escape (Smith 2012). Thus, although traditional bullying and cyberbullying are both behaviors that are intended to harm another person, there are specific features that distinguish cyberbullying from traditional bullying. However, despite the common definitional criterion of the intention to harm, other criteria like repetition of the act and power imbalance have been questioned (Menesini 2012; Pieschl, Porsch, Kahl & Klockenbusch 2013; Smith 2012).

Langos (2012) included the criteria of repetition only for special forms of cyberbullying—direct cyberbullying (where the communication of the perpetrator is directed to the victim straightly) as opposed to indirect cyberbullying (where the communication is spread in public cyberspace). She explained that “Cyberbullying involves the use of ICTs to carry out a series of acts as in the case of direct cyberbullying, or an act as in the case of indirect cyberbullying, intended to harm another (the victim) who cannot easily defend him or herself” (p. 288). Furthermore, in focus groups with youth from three countries (i.e., Italy, Spain, Germany), Nocentini, Calmaestra, Schultze-Krumbholz, Scheithauer, Ortega, and Menesini (2010) found that cyberbullying acts were labeled as such when the intention to harm of the perpetrator is related to experienced harm by the victim and when repetition of the act is present. Other criteria like the imbalance of power, anonymity, and publicity were not prerequisites for labeling an act as cyberbullying, but help to understand the specific context of the act (e.g., the severity of the attack). In sum, the intention to harm delivered via electronic means is the definitional core of cyberbullying, with repetition, power imbalance, anonymity, and publicity as additional criteria. Interestingly, the only definitional criteria that included the broader social context of cyberbullying was publicity (Nocentini et al., 2010) and indirect cyberbullying (Langos 2012), where the target of the degrading message is not only the victim but also potentially the public audience. This is relevant for the perspective of cyberbystanders, because it focuses on the public audience (i.e., the cyberbystanders) who constitute a specific feature of cyberbullying compared to traditional bullying.

CONCEPTUAL MODELS OF BYSTANDING IN TRADITIONAL BULLYING

Definition of Bystander

Considering the linguistic notion of the term bystander, a bystander is a person who is standing by or present at an event or incident without taking part as an onlooker, observer, or spectator (Oxford Dictionaries 2015). However, bystanders in traditional bullying are mostly seen as involved participants rather than passive witnesses of an event, because they can decide whether to get involved or stay uninvolved (Oh & Hazler 2009) and their behavior influences other people present in a way that reinforces or weakens the behavior of others (Salmivalli 2010). Referring to the pragmatics of human communication, it could be argued that every verbal, paraverbal or nonverbal behavior might be interpreted from other persons as a behavior with a meaning for them and therefore all behavior in social situations implies messages such that “one cannot not communicate” (Watzlawick, Bavelas & Jackson 2011, p. 30). In this sense of the impossibility of not communicating even when doing nothing, a bystanders behavior—be it passive or active, verbal or nonverbal, ambiguous or clear—can be interpreted by other persons in the situation as a communicative act. Therefore, a bystander is a person who notices a social situation occurring between at least two involved actors. Possibly there are more persons in this situation present, e.g., a group of bullies, victims, or other people who are not actively involved from the beginning. The two actors are the bully (or bullies) and the victim(s) in traditional bullying or the cyberbully (or cyberbullies) and the cybervictim(s) in cyberbullying, respectively. The term traditional bystander here is used to refer to bystanders in incidents of traditional bullying and cyberbystanders as bystanders in incidents of

cyberbullying. A cyberbystander is a person who notices a social situation occurring among a cyberbully and a cybervictim, and possibly other persons noticing this incident.

The group that is mostly researched as traditional bystanders are people from the peer group of the victim, e.g., classmates or schoolmates (Salmivalli, Lagerspetz, Björkqvist, Österman & Kaukiainen 1996). However, other groups could be considered as well, including teachers, educational or administrative personal in schools, parents, or even other people on the street or passengers in public transport (Fekkes, Pijpers & Verloove-Vanhorick 2005; Flashpohler, Elfstrom, Vanderzee, Sink & Birchmeier 2009). Research has shown that traditional bullying among children and adolescents not only takes place within schools but also beyond school yards (Wolke, Woods, Stanford & Schulz 2001); therefore, not only peer groups may constitute bystanders to traditional bullying.

The bystanders in cyberbullying may also include different people witnessing cyberbullying incidents online or offline, like peers from school and adults, like teachers and parents. These cyberbystanders may notice the cyberbullying incident online (e.g., while surfing on social networking sites, reading messages in a WhatsApp group, or watching degrading videos on a video portal) or offline (e.g., the cybervictim informs them, bystanders are physically present with the cyberbully or the cybervictim while it happens). Thus, there is a broad variety of people who may constitute a cyberbystander as well as a multiplicity of possible ways cyberbystanders can learn about the incident.

Cyberbystanding research so far has included mainly adolescent samples (e.g., Macháčková, Dedkova, Sevcikova & Cerna 2013), sometimes children (e.g., Van Cleemput, Vandebosch & Pabian 2014), young adults (e.g., Shultz, Heilman & Hart 2014) or teachers (e.g., Eden, Heiman & Olenik-Shemesh 2012). Because of the focus of existing research so far, the current chapter focuses mainly on research on adolescents if not otherwise indicated.

Bystanders in Social-Psychological and Developmental Psychological Research

The concept of bystanders has been researched from diverse theoretical views and in different contexts. Most traditional bullying episodes are social situations in nature, because in more than 80% of the cases uninvolved students are present when another student is harassed (Atlas & Pepler 1998; Hawkins, Pepler & Craig 2001; Rigby & Johnson 2006).

The bystander effect indicates that the probability of helping decreases with the higher the number of people present (Latané & Darley 1970; Latané, Nida, & Wilson 1981). More generally, the decision to help or not to help a person in need is conceptualized in a bystander intervention model (Latané & Darley 1970). This model specifies the steps which a witness takes to show or not to show helping behavior toward others in emergency situations. The model describes five key steps that must be taken by a bystander to intervene: (a) noticing that something is happening, (b) interpreting the event as an emergency, (c) taking personal responsibility for providing help, (d) choosing how to help, and (e) displaying helping behavior. The model assumes that at every step hindrances may occur which lead a bystander to stay passive and that every step has to be taken positively in order to help. The bystander intervention model has been successfully applied to situations of traditional bullying (e.g., Pozzoli & Gini 2012) as well as cyberbullying (e.g., Dillon & Bushman 2015).

Another very helpful approach to understand the social underpinnings of traditional bullying situations is the social identity theory (Tajfel & Turner 1986, cited in Mummendy & Otten 2002), which describes the interplay of individual behavior and social group dimensions influencing it. Social identity theory proposes that the behavior in social situations is based on a social categorization process between an in-group the person belongs to and an out-group the person is not part of. As people strive for a positive and distinct social identity, people in intergroup situations tend to favor the in-group (in-group-favoritism) in contrast to the out-group (out-group devaluation). People show the more in-group-favoritism the more strongly they identify with their own in-group. In addition, people show intergroup behavior like social competence (and maybe aggressive or bullying behavior) or social creativity, especially when relevant out-groups and evaluation dimensions are situationally available. The social identity theory has been fruitful in explaining social discrimination of individuals belonging to out-groups (Mummendy & Wenzel 1999), inspiring research to diminish prejudices and discrimination (Gaertner & Dovidio 2005; Pettigrew & Tropp 2008) and group processes in cyberbullying (Jones, Manstead & Livingstone 2011).

Building on insights concerning intergroup and socialization processes, a group socialization theory of development was proposed by Harris (1995). This theory emphasizes that socialization is context-specific and takes place inside and outside the home, where the peer group strongly influences individual development as well as the parents' peer group who transmit culture via group processes. Furthermore, between-group (in-group-favoritism) as well as within-group processes (social comparison) lead to assimilation to the group and differentiation from specific aspects of the group (Harris 1995). The focus on the peer group and inter- and intra-group-processes seems especially fruitful for researching cyberbystanding behavior.

Bystanders in Traditional Bullying

While research on traditional bullying mainly focused on personal characteristics of bullies and victims, there are three approaches focusing on the behavior of bystanders in traditional bullying, the socio-ecological model, the participant role approach (Salmivalli 2001), and the cycle of bullying (Olweus 2001).

In the socio-ecological model of bullying, the interplay of different factors on the probability of bullying and victimization is analyzed. For example, pro-bullying attitudes and negative school climate go along with high levels of bullying behavior (Swearer et al., 2006), and peers tend to make friends to other peers who are more similar to them regarding self-reported bullying and fighting, so pro-bullying and anti-bullying friendship groups emerge (Espelage, Holt & Henkel 2003). Socio-ecological theory analyzes factors at various levels—ranging from the individual, family, school, peer group, to community, and society. This enables a complex view on the determinants on bullying from various levels.

Conceptually, the social dimension of bullying as a group phenomenon is especially stressed by the participant role approach (Salmivalli 2001). For example, a seminal empirical study identified six typical behaviors or social roles which students adopt in the process of traditional bullying (Salmivalli, Lagerspetz, Björkqvist, Österman & Kaukiainen 1996). These so called participant roles were identified via peer nominations and include the roles of victims, bullies, assistants of the bully, reinforcers of the bully, defenders of the victim, and outsiders.

While the victim is a target of systematic harassment, the bully is actively taking the initiative for bullying behaviors. Assistants of the bully join in the bullying once it has started and assist the bully. Reinforcers of the bully behave in a way that encourages the bully; e.g., watching and laughing of bystanders can be interpreted as a social reinforcement following the social learning theory (Bandura 1973). Defenders of the victim take side with the victim and actively intervene in order to stop the bullying. Outsiders withdraw from bullying situations or do not react to the bullying (Salmivalli 2001; Salmivalli et al., 1996; Sutton & Smith 1999).

Olweus (2001) builds on the participant role approach and describes a cycle of bullying on the continuum of acting or not acting in a bullying situation. He differentiates the following roles or typical ways of behaving in the context of traditional bullying: bullies, followers / henchmen, supporters, passive supporters, disengaged onlookers, possible defenders, and defenders of the victim. In contrast to the participant role approach, these roles are based on theoretical considerations and (to the best of my knowledge) are not yet empirically validated. One great advantage of the participant role approach and comparable theories is their emphasis that bullying is not only a dyadic phenomenon between a victim and a bully, but is embedded in a social context and nearly all children in a group are either actively or passively involved in the bullying process.

The role of defender is crucial, because these children actively support the victim and try to stop the bullying. This behavior may be seen as civil courage which is a bystander's intervention associated with potential risks in a situation where fundamental norms are being violated (Pfetsch 2010). Research has shown that those students who defend the victim show high levels of affective empathy, and cognitive empathy, high social self-efficacy, well developed skills of social and moral cognition (i.e., high levels of understanding for cognitive, emotional, and moral states of others, and low levels of moral disengagement) (Gini, Albiero, Benelli & Altoè 2007; Gini, Albiero, Benelli & Altoè 2008; Gini 2006; Nickerson, Mele & Princiotto 2008). Furthermore, defenders tend to have high social status in their class, show high levels of agreeableness and emotional stability, and high self-esteem and report altruistic feelings (Lodge & Frydenberg 2005; Salmivalli et al., 1996; Tani, Greenman, Schneider & Fregoso 2003). Most of these determinants could be trained in order to enhance defending behavior or civil courage among students (Pfetsch 2010; Pfetsch, Steffgen, Gollwitzer & Ittel 2011). Apart from the role of the defender, also the assistants of the bully, reinforcers of the bully, and outsiders influence the process of traditional bullying, because their behavior is perceived either as a support for the bully or for the victim (Salmivalli 2001).

DETERMINANTS AND CORRELATES OF CYBERBYSTANDING BEHAVIOR

Research focusing on traditional forms of bullying shows that in more than 80% of the cases, uninvolved students are present when another student is harassed (Atlas & Pepler 1998; Hawkins, Pepler & Craig 2001; Rigby & Johnson 2006). The vast majority of youth disapprove of aggression and bullying at school (over 80%; Gini, Pozzoli, Borghi & Franzoni 2008; Menesini, Codecasa, Benelli & Cowie 2003; Pepler, Craig, Ziegler & Charach, 1993; Rigby & Slee 1991). Nevertheless, only one in four students reports that they have intervened in favor of a victim of bullying (Rigby & Johnson 2006) and one in five was observed doing so

(Hawkins et al., 2001). Concerning cyberbullying, one might ask, how often do cyberbystanders intervene in instances of cyberbullying and what determinants might influence how cyberbystanders perceive and behave in the context of the cyberbullying incident. In the following, different determinants and correlates of cyberbystanding behavior are presented. The first section refers to the different forms and prevalence rates of cyberbystanding behaviors, then findings from empirical studies concerning individual, social, and situational characteristics of cyberbystanding will be reviewed. If relevant, research on traditional bystanding is summarized, before findings on cyberbystanding are presented.

Prevalence and Form of Bystanding in Cyberbullying

Prevalence rates of cyberbystanding behavior differ. While around 53-55% of Canadian adolescents reported to know someone who had been cyberbullied (Li 2006, 2007), 35% of Flemish children and adolescents reported having witnessed cyberbullying, of which 59% stayed passive, 45% reported helping the victim, and 5% joined the cyberbully (Van Cleemput et al., 2014). In another study, 53% of Czech adolescents reported knowing someone who had been cyberbullied (Macháčková et al., 2015b). Other research revealed that 20% of German adolescents reported cyberbystanding behavior at least once a week or more often in the last year, of which 55% stayed passive (cyberoutsiders), 25% defended the cybervictim (cyberdefenders), and 21% helped to cyberbully others (cyberassistants; Wachs 2012). In a study conducted in Australia, 45% of the adolescents reported witnessing cyberbullying (or cyberbullying and traditional bullying) in the last year, of which 53% behaved as cyberoutsider, 31% as cyberdefender, 8% as cyberassistant, and 8% as cyberreinforcer in the last incident of cyberbullying (Quirk & Campbell 2014). In total, prevalence rates for cyberbystanders differ between 20% and 55%, possibly due to different methodology (formulation of questions, reference time frames or cut-off criteria), age ranges, or cultural differences.

Generally, researchers differentiate several forms of cyberbystanding behavior (Shultz, Heilman & Hart 2014), including supportive helpful cyberbystander behavior in favor of the cybervictim, reinforcing and degrading cyberbystander behavior by joining the cyberbully, and passive and ignoring cyberbystander behavior. These behaviors can be implemented either online or offline, either privately or publicly, and are addressed either to the cybervictims or to the cyberbullies. Defending the cybervictim can take several forms, like talking offline to the cyberbully, confronting the cyberbully online, providing advice to the cybervictim online or offline, reporting to a service provider, informing friends or adults (i.e., parents, teachers), frightening the cyberbully, or physical retaliation (e.g., DeSmet et al., 2014; Shultz et al., 2014).

Although passive cyberbystanding was perceived rather acceptable among Flemish adolescents (DeSmet et al., 2014), passive behavior can be recorded and displayed in metadata, like social networking sites, web sites, or instant messengers, through the number of views, the web counter of visits, or the read confirmations of messages and it may therefore can have a greater impact than passive offline bystander behavior. However, in other occasions it is less clear how we can measure and interpret passive cyberbystanding, as some adolescents in focus groups said that they did not react to the cyberbullying in order not to give attention to the cyberbully (“purposeful ignoring;” Pfetsch, & Ittel 2012). While conducted with a supportive motivation from the cyberbystanders, this behavior could be interpreted from others as a silent approval and thus reinforcing cyberbullying.

Some researchers have transferred the participant role approach of traditional bullying to cyberbullying, measuring the roles of assistants, reinforcers, defenders, and outsiders in the context of cyberbystanding (Quirk & Campbell 2014; Wachs 2012). However, DeSmet et al. (2014) argue that cyberbystanding behavior depends heavily on the context (friend vs. acquaintance as cybervictim, popular vs. unpopular cyberbully, clear vs. unclear circumstances, perceived fairness of the behavior of the involved parties). Therefore, cyberbystanding behavior varies more than in traditional bullying and should not be considered as fixed participant roles. Pfetsch, Müller, Walk, and Ittel (2014) found substantial overlap across self-reported cyberbystanding behavior, when participants could indicate one or more of cyberbystanding behaviors that applied for them in the last cyberbullying incident. 40% of the 428 adolescents were classified as having only one role (cyberdefender, cyberoutsider, cyberbully, or cybervictim), 34% were classified as having two roles, 18% three roles, and 8% four roles. It seems that the characteristics of the concrete situation are very powerful determinants of cyberbystanding behavior and that supportive, reinforcing, and passive cyberbystanding are not mutually exclusive, even in the same incident (Shultz et al., 2014). The situational influence on cyberbystanding will be examined later.

INDIVIDUAL CHARACTERISTICS

In the following section, empirical results concerning individual characteristics of cyberbystanders are reported. Depending on the measurement of cyberbullying, conceptualization of the bystander reactions, and other study features, results across studies differed.

Gender and Age

In traditional bullying, some gender and age differences were found (see Macháčková et al., 2015a). Generally, younger children tend to report that they are defenders or support the victims more often than older adolescents (Menesini et al., 1997; Pozzoli & Gini 2010; Rigby & Johnson 2006; Rigby & Slee 1991). Gender differences are not as consistent. While in some studies girls tend to defend more often than boys (Gini et al., 2007; Goossens, Olthof & Dekker 2006; Oh & Hazler 2009; Salmivalli et al., 1996), in other studies there were no difference (Menesini et al., 1997).

In cyberbullying experiences as bystanders, males tend to be cyberassistants more than girls, but they are less likely cyberdefenders (Quirk & Campbell 2014). In reaction to an experimental cyberbullying situation in social networking sites, adolescent girls were found to comfort the victim, give the victim advice, and defend the victim more often than boys (Baestiaenssens, Vandebosch, Poels, van Cleemput, DeSmet & De Bourdeaudhuij 2014). In contrast, boys were more inclined to tell the bully that they think the degrading picture is funny (Baestiaenssens et al., 2014).

In another experimental study, no gender differences concerning behavioral intentions could be proved. Girls and boys were equally inclined to report a hate group, support the victim, tell the bully to stop, do nothing or join the hate group—only regarding the option to contact

adults, girls report higher behavioral intentions (Fawzi & Goodwin 2011). No gender differences were found in forwarding a degrading picture in an experimental setting (Barlińska et al., 2013; Barlińska et al., 2015) as well as in supporting the victim as documented through self-reports of cyberbystander experiences (Macháčková et al., 2013; Macháčková et al., 2015a). Furthermore, results concerning gender differences were mixed concerning children's and adolescent's self-reports on cyberbystander behavior. Bivariate correlations showed that girls were more likely to help the victim (defenders) and less likely to do nothing (outsiders), but gender did not predict joining in, helping, or doing nothing when considered with other predictors simultaneously (Van Cleemput, Vandebosch & Pabian 2014). Taken together, results concerning gender differences across cyberbystanding behavior revealed an inconsistent pattern, possibly because of different methodology in the measurement of cyberbystander behavior (e.g., self-reports of experiences vs. experimental manipulation, classification into supportive, reinforcing and passive behavior), confounding variables like age of the participants or cultural differences (Macháčková et al., 2015a).

Concerning age differences in cyberbystanding behavior, some studies found no significant effect of age on supporting the victim (Macháčková et al., 2013; Macháčková et al., 2015a), whereas others found that older adolescents were more likely to join in the cyberbullying, to do nothing, and less likely to help the victim (Van Cleemput et al., 2014), and that, although there was a significant difference of the mean ages of cyberbystanders—slightly older cyberoutsiders than cyberdefenders—the difference was only a few months and probably without practical relevance (Quirk & Campbell 2014). It seems that results of age differences are not as consistent as in traditional bullying but seem to go in the same direction—children tend to help more, whereas adolescents tend to stay passive or even join in the cyberbullying, reinforcing it. This could be due to the fact that the concern about being accepted by their peers peaks in early adolescence (Bellmore, Ma, You & Hughes 2012), which can reduce the probability to intervene in cyberbullying incidents in order not to take sides and avoid tensions in the relationships (Van Cleemput et al., 2014).

Previous Involvement in (Traditional or Cyber-) Bullying or Victimization

Based on a hypothetical scenario involving a hate group in a social networking site against a classmate, 2,502 adolescents reported their behavioral intentions (Fawzi & Goodwin 2011). Those bystanders who had been former cybervictims were not more willing to support victims than other bystanders, whereas bystanders who had been cyberbullies before were more willing to encourage the perpetrator than other bystanders. In particular, they reported the group, supported the victim, and contacted an adult significantly less often than non-bullies. So, the previous experience as a cyberbully influenced bystander's intentions to react in a way that reinforced cyberbullying.

Regarding children's and adolescent's self-reports of cyberbystander behavior, joining in cyberbullying was predicted by reporting traditional bullying and cyberbullying behavior, helping the victim was predicted by victimization in traditional and cyberbullying, and doing nothing was negatively predicted by victimization in traditional bullying (Van Cleemput et al., 2014). While supporting and helping the victim was related to one's experience of victimization, reinforcing the bullying was related to one's experience of bullying.

Overlap of Bystanding in Traditional Bullying and Cyberbullying

Taking the similarities of traditional bullying and cyberbullying into account—intention to harm, repetition, power imbalance—it can be assumed that the roles bystanders take in online and offline bullying situations are quite similar. However, a total accordance seems unrealistic when considering the differences of cyberbullying in contrast to traditional bullying, e.g., physical and psychological distance, reduced emotional feedback, potential of an amplified publicity, and anonymity in the online context. Also, cyberbullying tends to be less frequent than traditional bullying (Tokunaga 2010). As such it is not surprising that a study with 518 adolescents who self-reported their behavior once a week or more often in the last year in the context of traditional and cyberbullying found that the roles in cyberbullying were a bit less frequent than the roles in traditional bullying (e.g., 8.5% traditional defenders vs. 5% cyberdefenders; Wachs 2012). Furthermore, there was substantial and significant overlap of the roles: 59% to 66% of the bullies, assistants, outsiders, defenders, and victims in cyberbullying situations were also bullies, assistants, outsiders, defenders, and victims in traditional bullying (Wachs 2012).

These findings differed slightly in a study with 930 (mainly female) early adolescents who self-reported their behavior in the most recent incident of traditional and cyberbullying that they experienced (Quirk & Campbell 2014). The overlap in cyberbullying roles to traditional bullying roles was 5% (of cyberreinforcers who were also traditional reinforcers) to 65% (of cyberoutsiders who were also traditional outsiders). While the overlap was considerably lower for roles of cyber-assistants and cyber-reinforcers (who both tended to be traditional outsiders), the roles of outsiders and defenders were clearly higher (Quirk & Campbell 2014). In total, there is considerable overlap between some of the roles in cyberbullying and traditional bullying (e.g., outsiders) whereas other roles were less stable across contexts (e.g., reinforcers).

Empathy

Empathy as the ability to understand (cognitive empathy) and feel the emotions of another person (affective empathy; Batson 2009) is considered a protective factor against aggression (Miller & Eisenberg 1988), antisocial behavior (Jolliffe & Farrington 2004) and traditional bullying (Mitsopoulou & Giovazolias 2015). Also, there is evidence that defenders of the victim in traditional bullying show high levels of affective empathy (Gini, Albiero, Benelli & Altoè, 2007; Nickerson, Mele & Princiotta 2008; Pöyhönen, Juvonen & Salmivalli 2010), cognitive empathy (at least the boys, Gini et al., 2007; Caravita, Di Blasio & Salmivalli 2009; Espelage, Mebane & Adams 2003), high social and moral cognition skills, and high levels of understanding for cognitive, emotional, and moral states of others (Gini 2006). In contrast, pro-bullies (assistants, reinforcers) reported lower levels of affective and cognitive empathy (Gini et al., 2007), and outsiders lower affective empathy (Nickerson et al., 2008).

Concerning cyberbystanders, the effect of situational activation of affective and cognitive empathy through a video presenting a case of cyberbullying was analyzed (Barlińska, Szuster & Winiewski 2013). A total of 1,498 adolescents saw the video with different instructions: seeing the video including victim's feelings (affective empathy), anticipating victim's emotions (cognitive empathy, instruction 1), anticipating victim's behavior in reaction to the harm (cognitive empathy, instruction 2; Barlińska et al., 2013), or focusing on the negative

consequences of cybervictimization for the victim (cognitive empathy, instruction 3; Barlińska, Szuster & Winiewski 2015). Participants then read a hypothetical scenario involving a comment on a degrading photo and had to decide whether they would forward the message or delete it. The analyses showed that the activation of state affective empathy and all three instructions for state cognitive empathy reduced negative bystander behavior (forwarding the degrading photo; Barlińska et al., 2013; Barlińska et al., 2015). However, focusing on the negative consequences of cybervictimization for the victim (cognitive empathy, instruction 3) reduced negative bystander behavior only immediately after the manipulation and not one week later (Barlińska et al., 2015).

In a study concerning real-life experiences of cyberbystanding among 453 adolescents, the factors that influenced the immediate empathic response towards the cybervictimization were analyzed (Macháčková et al., 2015b). Adolescents' empathic responses in the sense of the degree to which witnessing the cyberbullying did upset the cyberbystander was predicted by higher prosocial behavioral tendencies, a better personal relationship to the cybervictim and either being present when the event happened or being informed by the cybervictims about it. Macháčková et al. interpreted these findings by suggesting that the directness or proximity of the cyberbystander to the cybervictim and the incident heightens the empathic response. Furthermore, referring to the same data, the probability of actively supporting the victim was positively predicted by the immediate empathic response over and above prosocial behavior tendencies, self-esteem, or fear of intervening (Macháčková et al., 2015a). Other data from real-life experiences in children and adolescents corroborated that affective empathy (or empathic concern) predicted helping the victim and negatively joining in bullying as well as doing nothing in spite of noticing the bullying (Van Cleemput et al., 2014).

In sum, the results of these studies implied that actively taking the perspective of the cybervictim (cognitive empathy) and feeling the emotions of a harmed person (affective empathy) is related to more supportive intervention and less passive reactions in cyberbystanders. All these results refer to state empathy or empathic responses in the current situation (and not dispositional or trait empathy). However, there is also research showing that affective and cognitive trait empathy is related to less cyberbullying behavior. Cyberbullies reported lower affective empathy, affective media empathy, and cognitive media empathy than non-involved students, while they were reported by their peers to have less cognitive empathy than non-involved students (Pfetsch, Müller & Ittel 2014). It seems that empathy is one possible protective factor against negative online behavior (as cyberbully or passive cyberbystander) and increases the probability of prosocial online behavior (as supporting cyberbystander).

SOCIAL CHARACTERISTICS

After the individual characteristics, social features that influence cyberbystanding will be described, particularly the relationship between the cybervictim and cyberbully as well as group norms for bullying behavior.

Relationship to Cybervictim and Cyberbully

In traditional bullying, bystanders react depending on their former relationship and closeness to the bully or the victim. Both data on hypothetical scenarios (Bellmore et al., 2012; Lodge & Frydenberg 2005) as well as real experiences as a bystander of bullying (Bellmore et al., 2012; Oh & Hazler 2009) support this fact. When bystanders are friends with the victim, the probability to intervene as defenders and to try to stop the bullying is higher, while it is lower when bystanders feel closeness to the bully.

Referring to one's own experience as a bystander of cyberbullying, a good or at least a neutral relationship with the victim predicted bystanders' support of the victim (Macháčková et al., 2015a; Macháčková et al., 2015b). Furthermore, a positive relationship with the cyberbully was associated with less supportive behavior for the cybervictim (Macháčková et al., 2013). When other cyberbystanders were labeled as good friends in contrast to a mere acquaintance, the intention to reinforce the cyberbully by doing something similar is significantly higher. But when other cyberbystanders defended the victim, participants were less likely to reinforce the cyberbully when these other cyberbystanders were good friends (Bastiaensens et al., 2014). Also, qualitative research found that adolescents tend to defend cybervictims especially if they are good friends (DeSmet et al., 2012; Pfetsch, Ittel & Walk 2012). In addition, data on hypothetical scenarios showed that social identification with the cybervictim leads to more frequent supportive online behavior or confrontational intervention, while identification with the cyberbully is related to more passive bystander behavior or supportive offline behavior (Shultz et al., 2014).

In sum, mirroring the results of traditional bullying, in cyberbullying bystanders reacted to incidents of cyberbullying in a way that corresponded their established relationships with the cyberbully or the cybervictim. Possibly, behaving against a friend would endanger the relationship and, therefore, cyberbystanders support the person they have a closer relationship with.

Also, adolescents in pro-bullying roles in traditional bullying (bullies, assistants, reinforcers) shared attitudes that were more approving of bullying (Salmivalli & Voeten 2004) and tended to establish friendship networks ("homophily hypothesis;" Espelage, Holt & Henkel, 2003; Huitsing & Veenstra 2012). Therefore, in cyberbullying it might be possible that cyberbystanders who reinforced the cyberbully had more aggression-approving attitudes and friendships with cyberbullies. Existing relationships seemed to shape cyberbystanding behavior.

Group Norms for Cyberbystanding Behavior

In traditional bullying the classroom mean levels of reinforcing bystander behavior were related positively and the mean levels of defending behavior related negatively to bullying behavior (Salmivalli, Voeten & Poskiparta 2011). The behavior of the social context served as positive or negative feedback for bullying behavior and these results can be interpreted in a way that behavior of others can be seen as a normative influence on bullying behavior.

In cyberbullying, the influence of group membership and group norms on group-based emotions was analyzed with 90 children aged 10-11 years (Jones, Manstead & Livingstone 2011). Manipulating the norm of the perpetrator's group (to be kind or unkind towards others),

children were confronted with a scenario of cyberbullying. Results showed, that group membership, group norms, and the proposed antecedents of the group-based emotions of pride, shame, and anger (but not guilt) influenced group-based emotions and action tendencies. Identification with a kind or unkind perpetrator group led to different emotions (shame, anger) and behavioral intentions in cyberbullying (keep away from the perpetrator, saying sorry to the target, telling an adult what has happened). Also for bystanders in cyberbullying, the social norms and expectations from important others seemed relevant in predicting emotions and behavior towards the victim. However, there is still much research necessary to fully understand the group-based processes in the context of cyberbullying.

SITUATIONAL CHARACTERISTICS

The following section concerning the current state of knowledge about the situational determinants of cyberbystanding is organized by the five steps of the bystander intervention model, including (a) noticing the incident, (b) interpreting it as an emergency (and assessing its severity), (c) responsibility to help, (d and e) decision how to help and displaying helping behavior (Latané & Darley 1970). Afterwards, current knowledge on a specific social characteristic of a cyberbullying situation—how the number of bystanders present inhibits helping behavior in cyberspace (bystander effect)—is reviewed.

Noticing the Cyberbullying Incident

Using an experimental approach, the first step of a bystander intervention model from Latané and Darley (1970) was tested, i.e., the necessity to notice a cyberbullying incident occurring in a chat environment under different conditions of audio or visual distraction (Dillon & Bushman 2015). Noticing the event was operationalized via answering that a negative conversation (cyberbullying) happened on open questions in post-experimental interviews about a chat room and concerning feedback about the experiment in the funneled debriefing procedure. The distraction tasks had no effect on noticing the event or intervening. However, cyberbystanders were found to be more likely to intervene when they reported noticing that a negative conversation occurred compared to when they did not report negative experiences (which did not necessarily mean that they did not notice, but at least they did not report it). While the majority of the participants (68%) reported noticing the cyberbullying incident, only 10% intervened directly (chat comments towards the bully, victim or a non-present other), and 68% intervened indirectly after the incident (through worse evaluation of the bullies performance in the chat or notifying the researcher about insults occurring in chat; Dillon & Bushman 2015).

Interpreting the Cyberbullying Incident As an Emergency and Assessing Its Severity

It is difficult to assess the severity of a cyberbullying incident objectively, because different online situations can vary significantly concerning the medium of the harassment, public vs.

private context, amount of audience witnessing the incident, combination of online and offline acts (overlap to traditional bullying), possibility to be a bystander to cyberbullying online or offline, and relationship to involved parties. Therefore, when assessing the severity of a cyberbullying incident, it is important to take into account the perspectives of cybervictims (Pieschl, Kuhlmann & Porsch 2015).

Obermaier, Fawzi, and Koch (2014) conducted two online experiments with adult participants regarding hypothetical cyberbullying scenarios in social networking sites, manipulating the number of bystanders (2 vs. 5,025 bystanders) and the degree of severity of the cyberbullying incident with more subtle insults vs. very rude and harsh insults (medium vs. highly severe). In this study, a higher severity led to a higher assessment of the situation as an emergency. The assessment of the situation as an emergency was positively linked to a higher intention to intervene in cyberbullying. This relationship was mediated through higher feelings of responsibility of the bystanders to help. Thus, noticing the incident and interpreting it as an emergency that calls for action significantly heightened the probability to intervene in cyberbullying incidents.

Also, Bastiaenses et al. (2014) manipulated experimentally the severity of an incident, with a medium (insult on a public social networking site) and a high severe incident (publishing a degrading picture with mean comments on a public social networking site). The higher the degree of severity, the more likely early adolescents were to comfort the victim, report the incident, and defend the victim. However, severity was not related to different forms of reinforcing the cyberbully, like spreading the incident, doing something similar, or telling the cyberbully it is funny. Referring to self-reported bystander behavior in real cyberbullying situations, adolescents reported in focus groups that the more severe the incident was, the more probable they would intervene (Pfetsch & Ittel 2012). The severity was defined by the participants regarding the number of cyberbystanders witnessing the incident and the degree of physical harm to the cybervictim (e.g., in happy slapping incidents). In sum, these results implied that cyberbystanders tended to help the victim more, the higher the severity of the incident was evaluated. However, severity may not be directly linked to less reinforcing bystander behavior.

Responsibility to Help

As mentioned above, the medium vs. high severe cyberbullying incident in an experimental design led to a higher assessment of the situation as an emergency. The lower the number of bystanders and the higher the assessment of the situation as an emergency, the higher the feeling of responsibility was, which led to a higher intention to intervene in favor of the victim (Obermaier et al., 2014).

Other studies researched the attribution of responsibility for the cybervictimization to the victim ("blaming the victim"), a processes that has been repeatedly shown in the context of victims of (sexual) violence and that is connected to less helping behavior and more aggressive behavior towards the victim (Bohner, Eyssel, Pina, Siebler & Viki 2009). For example, one study analyzed the effects of different degrees of personal information disclosed on a social networking site (low vs. high) and extraversion of the victim (low vs. high) on blaming the victim among 586 young adults, aged 16 to 22 years. Results showed that a high degree of personal information disclosure and extraversion led to higher direct and indirect blaming of

the victim (Weber, Ziegele & Schnauber 2013). A study with 1,105 early adolescents more specifically measured the attributions of control, responsibility, and blame towards a cybervictim who reacted passive, active, or reactive to an incident involving embarrassing pictures and hurtful comments on a social networking site. If the cybervictim tried to ignore the situation (passive response), he or she was perceived as having more control and assigned greater blame than if he or she reported the incident (reactive response; Holfeld 2014). Male participants tended to attribute more responsibility and blame to the cybervictim than female participants. Taken together, victims of cyberbullying are evaluated by cyberbystanders as being partly responsible for their negative experience because of their behavior (information disclosure, passive response to cybervictimization) or personality (extraversion). These attributions of responsibility might hinder cyberbystanders to intervene to support the victim. On the other hand, the more responsible cyberbystanders feel to intervene, the higher their intention to actively support the cybervictim.

Decision on How to Help and Displaying Helping Behavior

In order to come to a decision to help or not to help, traditional bystanders might consider different reasons that speak in favor for an intervention that were outlined by Thornberg, Tenenbaum, Varjas, Meyers, Jungert, and Vanegas (2012). Based on semi-structured individual interviews with 30 students ranging from 9 to 15 years, the authors developed a conceptual framework of bystander motivation to intervene in traditional bullying. This framework encompassed five general motives to intervene: interpretation of harm in the bullying situation, emotional reactions, social evaluating, moral evaluating, and intervention self-efficacy. The interpretation of harm implied that bystanders would intervene more often in cases with a high severity causing significant harm to the victim. Emotional reactions included motivating reactions (empathy for the victim) as well as demotivating reactions (fear of being victimized, audience excitement). Social evaluating refers to a positive or negative relationship to the victim as well as the low vs. high social rank of the bully which resulted in high vs. low probability to intervene. Moral evaluating means the judgment of bullying being morally wrong and being responsible for intervening, whereas a high intervention self-efficacy could strengthen the intention to help a victim in need.

DeSmet et al. (2014) showed that the decision on how to defend a cybervictim or not depends on different contextual factors. A friend should always be defended, but when the cybervictim is an acquaintance it depends on the social status of the cyberbully—defending is more likely with an unpopular than with a popular cyberbully. However, a loner will not be defended, regardless of the circumstances. When cyberbullying is perceived as unfair (e.g., racist remarks, picking on appearance, or handicap), defending is more likely.

Whether a cyberbystander actually displayed active helping behavior in favor of the victim depends in part on the subjective assessment of resources to do so and in part on the social circumstances where the helping behavior should be shown. The fear of being negatively judged by an audience (evaluation apprehension) might diminish the probability of actually helping (Latané & Darley 1970). Also the perceived self-efficacy of helping the victim seemed to be a crucial determinant promoting the intervention, as shown in traditional bullying (Cappadocia, Pepler, Cummings & Craig 2012; Gini, Albiero, Benelli & Altoè 2008; Thornberg & Jungert 2013).

Bystander Effect in Cyberbullying

As noted above, there is a substantial discrepancy between a general attitude towards traditional bullying and displayed behavior. This might be explained by various factors, among others the bystander effect (Latané & Darley 1970). The probability offering help in an emergency situation decreases with the number of people witnessing the event (Latané & Nida 1981). Meta-analytic evidence showed that the bystander effect is reduced when the situation is perceived as being markedly dangerous for the victim and when the perpetrator is present in the situation with the bystander (Fischer et al., 2011). The bystander effect takes place in digital communication over chats (Markey 2000), social networking sites (Martin & North 2015), or e-mail-lists (Barron & Yechiam 2002; Blair, Thompson & Wuensch 2005).

More specifically concerning the bystander effect in cyberbullying, in the past years, several studies analyzed the influence of the number of others on the reaction to witnessed cyberbullying. Regarding hypothetical cyberbullying scenarios, no direct effect of the number of bystanders (2 vs. 5,025 bystanders) on the intention to intervene emerged. However, there were two significant mediation processes. The larger the number of bystanders, the less participants felt responsible to help and the less willing they were to intervene. Furthermore, the higher the severity of the cyberbullying incident, the more participants assessed the situation as an emergency, which led to higher feeling of responsibility and intention to intervene in the cyberbullying incident (Obermaier et al., 2014, Study 2).

The bystander effect was found when adolescent respondents reported their own response to witnessed cyberbullying attacks in the internet. Compared to just a few (“one or two”) bystanders present when the incident happened instead of a large number of bystanders (“a lot”), participants reported significantly less supportive reactions like comforting the victim (Macháčková, Dedkova & Mezulanikova 2014; Macháčková, Dedkova & Mezulanikova 2015c). Interestingly, only the smallest number (“one or two”) and not a medium number of bystanders (“under 10”) differed from a large number of bystanders (“a lot”), indicating a nonlinear relationship between bystanders and reduced helping behavior. Also the relationship between the number of cyberbystanders (2, 24, 224, 5,025) and the feeling of responsibility (Obermaier et al., 2014) indicated a non-linear function between the bystander number and the feeling of responsibility or intention to intervene. Although in these studies rather non-dramatic help was searched for, it seems clear that the number of people present in cyber space has an impact on the willingness to help another person.

Latané and Darley (1970) proposed several explanations for the occurrence of the bystander effect (see Dovidio, Piliavin, Schroeder & Penner 2006). One mechanism is diffusion of responsibility, which means that bystanders subjectively attributed responsibility to help to all bystanders while reducing their own contribution for helping. Secondly, pluralistic ignorance might take place when an event has to be assessed as an emergency. When confronted with an unexpected situation, people tended to orientate themselves to the behavior of others. When these others behave passively, one might infer erroneously that the event is not an emergency. Thirdly, evaluation apprehension might lead bystanders to behave passively in fear of embarrassing themselves in public. Except for the first mechanism, the diffusion of responsibility, these mechanisms still await empirical evidence in the context of bystanders of cyberbullying.

CONCEPTUAL FRAMEWORK OF CYBERBYSTANDING

After the overview on relevant conceptual approaches and empirical results, I describe a conceptual framework that encompasses relevant dimensions for the perceptions and behaviors of cyberbystanders. This framework is applicable for the analysis of dimensions underlying cyberbystanding (e.g., for considering central aspects of the situation of cyberbystanding or to identify possible control variables in studies about perceptions and behaviors of cyberbystanders) as well as for practical contexts (e.g., to understand the complexity of supportive or negative cyberbystanding behavior). The proposed conceptual framework of cyberbystanding is grounded in parts on prior research, e.g., concerning social identity theory or social relationships between cyberbystanders and cybervictims, but has to be proven empirically. Hopefully, the suggested dimensions and assumed relations to the cyberbystanding behaviors can be analyzed and validated in future studies.

Figure 1. Dimensions of bystanding in cyberbullying.

Cyberbystanding differs from traditional bystanding in three important aspects. The interplay of virtuality, or online and offline cyberbystander behavior is relevant, as well as the low vs. high proximity in three dimensions—temporal, technical, and psychological proximity. Furthermore, the social relationship dimension includes the existing relationship to cybervictim, cyberbully, or other cyberbystander as well as their social identity (in-group, out-group) and the number of cyberbystanders (see figure 1). These determinants of cyberbystanding perceptions and behavior is further explained below.

Virtuality: Online vs. Offline Cyberbystanders

Bystanders may be present in cases of cyberbullying in two forms, online and offline. Online cyberbystanding involves a person who notices cyberbullying using digital

communication technology such as the internet or mobile phones. Offline cyberbystanding involves a person noticing cyberbullying in the physical presence of others. *Online cyberbystanders* witness cyberbullying of others while being online, using the internet (e.g., websites, chat rooms, social networking sites, e-mail, instant messaging services) or using their mobile phone (e.g., phone calls, text messages, sending and receiving pictures or video clips). Examples of cyberbullying that might be witnessed online are reading how someone is spreading rumors in a chat room or receiving via mobile phone an embarrassing film (e.g., happy slapping).

In table 1, the presumed influence of virtuality on the behavior of cyberbystanders is displayed. Whether an online cyberbystander reacts supportive towards the victim, ignoring the incident, or reinforcing by joining in the bullying may be the function of many variables, e.g., proximity and social relationships. Possibly, the probability to behave by ignoring cyberbullying is higher in a public or semi-public area of the internet (e.g., social networks, chat rooms), because of the bystander effect. In a more private online environment, like a closed small group in a forum or a instant messenger group, the probability that cyberbystanders will behave by actively supporting the cybervictim might be higher, because of the higher responsibility to help of the individual bystander.

Table 1. Influence of virtuality on cyberbystanding behavior

Virtuality		Reinforcing	Passive	Supportive
Offline	in presence with cyberbully	High	Medium	Low
	in presence with cybervictim	Low	Medium	High
Online	(semi-)public	Medium	High	Low
	private	Low	Medium	High

Offline cyberbystanding takes place when the cyberbully acts aggressively against a cybervictim in the real-life presence of bystanders, e.g., the cyberbully uses the internet or his or her mobile phone to harass the victim and others see or hear it. Offline cyberbystanders may witness how a cyberbully makes an abusive phone call or how a bully edits degrading photos or videos. Depending on from whom offline cyberbystanders learn about the cyberbullying, cyberbystanders may react differently. If they are offline with the victim, they may behave in an active, supportive way towards the victim or stay passive. If they are in offline with the cyberbully, offline cyberbystanders may either stay passive or even join in the bullying. However, this assumptions about the influence on the behavior of cyberbystanders await empirical validation.

There are cases of cyberbullying that happen without any bystanders witnessing it (e.g., harassment in direct communication between cyberbully and cybervictim, i.e., direct cyberbullying; see Langos, 2012). The victim may talk to a peer, parent, or teacher about the negative experience and this person becomes a bystander.

Temporal, Technical and Psychological Proximity

The difference between online and offline cyberbystanders is connected to the degree of proximity of cyberbystanders to other involved people in the situation. Proximity may be

considered under three dimensions, temporal, technical, and psychological proximity. The assumed relationship between these dimensions of proximity and cyberbystanding behavior is shown in table 2.

Table 2. Dimensions of proximity and cyberbystanding behavior

Proximity	Reinforcing	Passive	Supportive
Temporal proximity	High	Low	High
Technical proximity	High	Low	High
Psychological proximity	High when proximity with cyberbully	Low	High when proximity with cybervictim

Temporal proximity means that the cyberbystander learns about the cyberbullying directly when it happens (e.g., in a chat room or via an instant messaging service) or more indirectly, if there is a time lag between the act of cyberbullying and the awareness of this act through the cyberbystander (e.g., reading degrading posts on a social networking sites many weeks later after they had been written). The incident can still be ongoing or be finished; however, it is not always easy to determine this from the side of the bystander, because information about cyberbullying incidents can be available for very long time on the internet. The probability that cyberbystanders react supportively or reinforcing the cyberbully is higher with a higher temporal proximity. In addition, cyberbystanders may react more often passively, the lower the temporal proximity (i.e., there is a bigger time lag between the cyberbullying act and noticing the incident by the cyberbystander). Thus, a perception of temporal proximity could lead to a higher feeling of urgency to intervene.

Technical proximity implies more realistic displays of communication (e.g., through a video on a video broadcasting channel) in contrast to more abstract displays of content (e.g., in text messages). The higher the technical proximity, the higher the realistic display, and the more cyberbystanders tend to act supportively or by reinforcing, but the lower technical proximity, e.g., in mere text messages, the more cyberbystanders tend to act passively. The more realistic the display, the more emotional cues can help a bystander to identify the emotions of the involved parties and, therefore, feel empathy for the victim, which might lead to more helpful behavior.

Psychological proximity means the degree to which a bystander experiences a situational social-emotional bond to the involved people like the cybervictim, cyberbully, or other cyberbystanders. Different from longer lasting social relations, psychological proximity means the situational feeling of connectedness to the other people. Normally a low temporal and technical proximity will go along with a low psychological proximity and a high temporal and technical proximity will imply a high psychological proximity (although this might differ). Presumably, with a higher psychological proximity to the cybervictim, cyberbystanders may support the victim, whereas with a higher psychological proximity to the cyberbully, cyberbystanders may be inclined to join in the bullying.

Social Relationship

The social relationship dimension includes the existing relationship from the cyberbystander to cybervictim, cyberbully, or other cyberbystander in the form of a positive

relationship (*friendship*) or a non-existing or negative relationship. As outlined above, cyberbystanders tend to react to incidents of cyberbullying correspondingly to their existing relationships with the cyberbully (joining in) or the victim (actively supporting the victim). This relationship between friendship and cyberbystanding behavior is shown in table 3.

Table 3. Interplay of social relations and cyberbystanding behavior

Social Relations	Reinforcing	Passive	Supportive
Friendship	Friendship with cyberbully	No pre-existing relationship	Friendship with cybervictim
Social Identity	Cybervictim as out-group, Cyberbully as in-group	Cybervictim and Cyberbully as out-group	Cybervictim as in-group, Cyberbully as out-group
Bystander Effect	High number of reinforcing bystanders	High number of passive bystanders	Low number of any bystanders

Furthermore, the *social identity* of the other involved parties is relevant to the behaviors of cyberbystanders. The perception of a cybervictim as an in-group member may lead to high psychological proximity (and active support), whereas a perception of a cybervictim as an out-group member may lead to low psychological proximity (and passively ignoring cyberbullying or reinforcing by joining the bullying). On the contrary, when the cyberbully is perceived as an in-group member reinforcing behavior becomes more probable, while a perception of the cyberbully as an out-group member might make it probable that cyberbystanders might support the cybervictim. However, if the cyberbystander perceives both, cybervictim and cyberbully, as out-group members, passive behavior might result. The social identity seems especially relevant, when the involved people are unknown to the cyberbystander and group membership and group characteristics are salient in the situation.

Finally, as the research on the *bystander effect* in cyberbullying has shown, the question about how many bystanders witnessing the incident affect the responses of individuals to cyberbullying. Apparently, there is a non-linear function between the number of cyberbystanders and the feeling of responsibility to intervene as well as the willingness to help another person. When there is a large number of (reinforcing or passive) bystanders, an individual might be inclined to behave in a reinforcing or passive way. On the other hand, when only a small number of bystanders is present, an individual tends to behave by actively supporting the victim.

This proposed conceptual framework for the perceptions and behaviors of cyberbystanders focuses on three main dimensions: (a) Virtuality as the online and offline location of the cyberbystander during noticing the cyberbullying, (b) Proximity as the temporal, technical, and psychological closeness of cyberbystanders to the involved people (cyberbully, cybervictim and other possible cyberbystanders), and (c) Social relationships which refer to the existing relationship of the cyberstander to the cybervictim and cyberbully and their perceived social identity and the number of cyberbystanders. These dimensions are central factors influencing perceptions and behaviors of cyberbystanders that are specific for cyberbystanding as opposed to traditional bystanding.

MILESTONES AND DIRECTIONS OF FUTURE RESEARCH

Research on the phenomenon of cyberbullying has started only about ten years ago and became very dynamic in the last years. Apart from a variety of themes dealt with—prevalence rates and overlap with traditional bullying, determinants and consequences of cyberbullying, risk and protective factors for cybervictimization, coping with victimization experiences, prevention of involvement in cyberbullying—research has also focused on cyberbystanders and how their behavior can be explained.

In contrast to cyberbullying research in general (Tokunaga 2010), there are several studies on cyberbystanders grounded on well-established theoretical models and applying appropriate methods to analyze these models. There are thorough applications of theoretical models like the bystander intervention model (Macháčková et al., 2015c; Obermaier et al., 2014), attribution theory (Holfeld 2014), or social identity theory (Bastiaenses et al., 2014; Jones et al., 2011) to the research of cyberbystanding behavior. Hopefully, more of those theoretically well grounded studies are conducted in future research. There are different constructs or research participants that are less researched or not researched at all so far in cyberbystanding: self-efficacy for intervening as a cyberbystander, moral emotions, moral disengagement and norms, psychological proximity of the bystander towards cybervictim and cyberbully, offline bystanders of cyberbullying (e.g., in physical presence of the cyberbully or cybervictim) or teachers and parents as bystanders of cyberbullying, to name just a few interesting themes. And this might even be a small selection on what future studies can focus.

Methodologically, current research so far has implemented mainly three approaches. Participants self-report their cyberbystanding behavior retrospectively, they are experimentally confronted with hypothetical scenarios about a cyberbullying incident and reactions to these scenarios are measured, or participants are interviewed qualitatively concerning their experiences and views on cyberbullying. All three approaches have their merits and disadvantages. The use of self-reports is highly ecologically valid and reflects the diversity of cyberbystanding situations. However, it can not be guaranteed that participants are able and willing to report the attitudes, motives and behaviors of cyberbystanders exactly, due to recall biases, self-serving biases, and social desirability. Experiments can control for confounding variables as well as manipulate the situation systematically in order to analyze causal relationships between study variables. Nevertheless, they have to reduce complexity of the phenomenon of cyberbystanding and their ecological validity is therefore reduced. Qualitative studies, on the other hand, have the strengths that individual reasons, circumstances or attitudes can be clarified and analyzed in-depth and that they are more open to new ideas and perspectives. However, they are not as representative due to smaller sample sizes and less standardization. To a lesser extent, research has used peer-reports, teacher- or parent-reports in order to measure cyberbystanding behavior (see Badaly, Duong, Ross, & Schwartz 2015). This might be due to the fact, that these groups do not share each and every situation and therefore peers, parents or teachers might lack of an informational basis they can draw on when they are asked to report on a cyberbystanders behavior. Further, observational studies in chat rooms, social networks, etc. are a possible alternative research methodology. This could include also the analysis of meta-data provided from service providers, such as the number of views, web counter of visits, or read confirmations of messages. This might affect ethical questions about data protection regulations and the right for privacy, although some of these data are available

publicly. Also, there is a lack of longitudinal studies, which could confirm how effective the behaviors of bystanders are and to what outcomes they may lead on side of the cybervictim. This could also be researched by applying social network analyses to follow up relationships between cybervictims, cyberbullies and cyberbystanders (see Festl, Scharkow & Quandt 2013). In addition, prevention studies on cyberbystanders could inform practitioners how to utilize the large potential of cyberbystanders in diminish cyberbullying. Although there is interesting and creative research in the field of cyberbystanders, as confirmed by the overview on empirical studies in this chapter, there is still a myriad of themes and methodologies waiting to be used for future research. So hopefully, future research will contribute to this inspiring research field in order to further our understanding of the behaviors of cyberbystanders.

Chapter 10

THE ADOLESCENT-PARENT CONTEXT AND POSITIVE YOUTH DEVELOPMENT IN THE ECOLOGY OF CYBERBULLYING

East Lansing, MI, US

²Northeastern University, Boston, MA, US

INTRODUCTION

An increasingly serious concern for many youth negotiating the normative challenges of adolescence involves the threat of cyberbullying. A full understanding of the dynamics of cyberbullying and the development of effective interventions requires an appreciation of the contributions of the multiple contexts, or the ecology of cyberbullying, including the family, the peer group, the school, and the neighborhood/community (Barboza et al., 2009; Espelage & Swearer 2011). Given the centrality of school experiences and peer relationships in the lives of adolescents, considerable attention has been directed at the school and peer context of cyber bullying (Barboza 2015). Much less research attention, however, has been directed towards the equally powerful and relevant family context of both face-to-face and cyberbullying.

With reference to the role of the family context in cyberbullying, it is useful to recognize that many adolescents participate in multiple microsystems involving interpersonal contact that includes in-person interactions (e.g., school, family or peer based), virtual contact (e.g., social media, not location specific), or some combination of both. In turn, understanding the dimensions of both the virtual experience of adolescent participation in social media and the adolescent participation in the family context are relevant to understanding and preventing cyberbullying victimization in a variety of interpersonal interactions.

* Corresponding Author's Email: schiambe@msu.edu.

Using the ecological perspective to bullying as a guiding framework (Barboza, Schiamberg et al., 2009; Espelage and Swearer 2011), this chapter will focus on the adolescent-parent relationship as the immediate and focal context (i.e., the microsystem) of cyberbullying (Veenstra et al., 2007). A review of research will in turn examine the critical dimensions of that context in relation to cyberbullying, including: (a) social factors and social media, which frame the adolescent parent context, (b) characteristics of the microsystem participants - adolescents and parents, (c) factors which influence the quality of the adolescent-parent relationship, and (d) contributions of contexts of adolescent experience beyond the adolescent-parent microsystem. The latter includes research connecting bullying and cyberbullying to the presence/absence of resources and developmental assets (e.g., individual characteristics and connection to external supports, including the family and community resources), frequently associated with Positive Youth Development (PYD) (Benson et al., 2004; Lerner et al., 2005).

A SOCIAL FRAMEWORK FOR ADOLESCENT-PARENT RELATIONSHIPS

Rapid advances in communication technology (e.g., the continuing evolution of cell phones, and computers) lends importance to developing a comprehensive yet somewhat fluid definition of cyberbullying. This is essential given the multiple ways that cyberbullying is defined (and reported), in turn complicating the accuracy of comparisons of the prevalence and correlates of cyberbullying across different studies. Other factors which inform the challenge of defining cyberbullying include the following: (a) the variation in age, gender, and other demographic characteristics across the samples studied, and (b) the need to sort out the elements of a cyberbullying definition which are shared/not shared with definitions of traditional face-to-facebullying.

PREVALENCE OF CYBERBULLYING

According to Aricak (2008), in the U.S., 91% of 58,273,000 children under the age of 18 are computer users, and 59% are Internet users. Twenty three percent of preschoolers (who are younger than five years old) were reported to be Internet users as well. Almost 8 out of 10 adolescents connect to the Internet from their home (Mason 2008; Lenhart, Madden & Rainie 2006). According to Schneider, O'Donnell, Stueve, and Coulter (2012), 93% of teens are active Internet users and 75% own a cell phone, up from 45% in 2004. Therefore, cyberbullying can be considered invisible because of its potential to harass victims outside of the classroom and school campuses.

With statistics such as these, it is not surprising that the rates for cyberbullying are alarming. For example, in a study involving 3,767 students in the U.S., 11% of respondents were victims of cyberbullying, 7% were cyberbullies -cybervictims, and 4% were cyberbullies, at least once over the previous several months (Kowalski and Limber, 2007). Approximately half of the victims had no knowledge of the identity of the cyberbully. As well, the data indicated that 53.2% of respondents indicated that the cyberbully was from their school and 37% reported that the cyberbully was their friend. In a 2007 panel study involving 13-17 year olds, 43% had experienced cyberbullying in the previous year (Wolak, Mitchell, & Finkelhor

2007). Hinduja and Patchin (2008) found that over 32% of boys and 36% of girls have been the victims of cyberbullying. A study by i-SAFE (2004) on 1,500 U.S. students in grades 4 through 8 found that 42% of students reported being bullied while online, and one in four reported that this happened on more than one occasion. Fifty-eight percent indicated that another person said mean or hurtful things to them online, with more than four in ten indicating that this happened more than once. Taken together, these results point to a disturbing prevalence of cyberbullying.

As might be expected, being online is associated with the likelihood of cyberbullying. In a study of 384 individuals under the age of 18, 11% reported bullying others while online and 29% reported being the victim of online bullying (Patchin and Hinduja, 2006). Cyberbullying was most prevalent in chat rooms along with text messaging and e-mail. As well, while online, 50% reported that they felt that they were not respected, 30% reported being called names, 21.4% reported being threatened by others, 19.8% reported being humiliated, and 18.8% reported having rumors spread about them. Results of another study with adolescent girls found that 68% of the time the bully was a friend or an acquaintance whom they knew from school while 28% of the time the bully was from a chat room (Burgess-Procter, Patchin & Hinduja 2008). Thirty six percent of the students in Ybarra, Diener-West and Leaf's (2007) nationally-representative sample reported that they were concurrently subjected to traditional bullying and cyberbullying. Higher rates were found by Juvonen and Gross (2008), with as many as 85% of adolescents who experienced cyber bullying were also victims of traditional bullying at school.

Likewise, Li (2006) found in a sample of 264 Canadian junior high school students, that one in four of these students had been cyberbullied and almost half of the students knew someone who was being bullied. Li (2006) also found that 54% of the students were victims of face-to-face bullying and over a quarter of them had been cyberbullied. One in three students had bullied others in traditional bullying, and almost 15% had bullied others using electronic communication tools. In the U.K., a study found that one in four 11 to 19 year olds reported that they had been the victim of cyberbullying (NCH, 2002). The most common medium through which cyberbullying was perpetrated was via text messaging on cell phones (NCH, 2006). Furthermore, a survey conducted by the National Crime Prevention Council found that of the more than 40% of U.S. teenagers who were cyber bullied, only about 10% told their parents about their experience (UPI, 2008).

CHARACTERISTICS OF CYBERBULLYING: INFLUENCE ON THE ADOLESCENT-PARENT MICROSYSTEM

Bullying is seen as intentional behavior that causes repeated harm to another individual. The victim of the bullying finds it difficult to defend himself or herself (Olweus 1993; Slonje, Smith & Frisen 2013). The advancement in technology has resulted in a transformation of bullying from the physical world to the virtual world (Ang & Goh 2010; Appel, Stiglbauer, Batimic & Holtz 2014; Aricak et al., 2008; Beale & Hall 2007; Beran & LI 2007; Rideout, Foehr & Roberts 2010). Traditional bullying stops at school. In the case of cyberbullying, the bullying occurs in cyberspace and through technological devices. Cyberbullying can follow a victim home via his or her cell phone and computer (Strom & Strom 2005). Cyberbullying uses the Internet and other technology willfully as a medium to transmit harm and discomfort

intentionally and repeatedly at a specific person, group, or persons (Jones, Mitchell & Finkelhor 2013; Li & Ang 2012; Ybarra & Mitchell 2004; Ybarra, Diener-West & Leaf 2007). It includes negative behaviors, such as lying, threatening, teasing, insulting, and displaying others' pictures without their consent in virtual settings (Belsey 2005; Monks, Robinson & Worlidge 2012; Sakeyari, Carroll & Houghton 2012; Williams & Guerra 2007). In traditional bullying, school administrators and teachers are considered to be the regulators of bullying (Holt & Keyes 2004). This is not the case in cyberbullying as the Internet is used because it provides a sense of anonymity to the perpetrators and, as well, there is limited monitoring by adults and parents. The use of technology reduces the sensitivity an individual has toward others in his or her surroundings.

Three Components of Face-to-Face Bullying Shared with Cyberbullying

There are many different definitions of cyberbullying in the literature, and many of these definitions come from the traditional bullying definitions. All of the definitions, however, share the common component of repetition of harm, hostility, and aggression that is directed toward the victim, via an electronic device or through the Internet (Tokunaga 2010). The definition of traditional bullying has three components: repetition of the harmful behavior, a power imbalance between the bully and his or her victim, and intent to harm. These three components are also evident in cyberbullying. However, the anonymity and pervasiveness of cyberbullying makes the detection of each of these components more difficult. The repetition of harmful behavior represents acts of cyberbullying that might spiral out of control, due to the technology used. Repetition is difficult to operationalize in cyberbullying. For example, if a picture is uploaded online, that picture can be distributed by other people. Repetition is created through the ongoing humiliation resulting from the embarrassing picture (Dooley et al. 2009; Fauman 2008; Leishman 2005). In the context of cyberbullying, this refers to an individual's greater knowledge of technology, Internet, and computers (Smith et al., 2008; Vandebosch & Van Cleemput 2008). Power can also come in the form of the anonymity of the Internet. It is more difficult for the victim to respond effectively if he or she does not know the bully's identity (Raskauskas 2010; Slonje & Smith 2008). Finally, Dooley, Pyzalski, and Cross (2009) state that the victim can feel powerless because the material that is posted online can be hard or impossible to remove. The victim is harmed psychologically, emotionally, and/or socially. Also, the behaviors must involve psychological torment and be carried out with harmful or malicious intent (Dehue, Bolman & Vollink 2008).

The Dynamic Features of Cyberbullying and the Adolescent-Parent Relationship

In addition, three features of cyberbullying, including anonymity, asynchronicity, and accessibility, pose advantages for cyberbullies, increasing risks for victims of cyberbullying and, in turn, challenges the adolescent-parent relationship as a source of support and prevention of cyberbullying. Anonymity refers to the absence of in-person audiovisual information (e.g., nonverbal cues) in communication and/or to the possible absence of cyberbully identity and, therefore, the source of cyberbully statements. In turn, such anonymity is a source of cyberbully

advantage and power. Cyberbully power is derived, not from having an in-person physical or psychological advantage, as in traditional bullying, but rather through their technological competence and their ability to hide their identity while online. Their ability to hide their identity provides cyberbullies with a safe haven, in turn not having to be bear the consequences of cyberbullying. Cyberbullies often engaged in cyberbullying because they knew that there would be no consequences resulting from their cyberbullying behavior (Holtz & Appel 2011; Lee & Chae 2007; Vandebosch & Van Cleemput 2008). Anonymous cyberbullies can transmit a personal attack in seconds (Garringer 2008). As Cooper (2004, p. 1) states, “the Internet has unleashed its dark side, an underground adolescent world of spite and vengeance. It is the bathroom wall moved into everybody’s bedroom.” Asynchronicity refers to the time allowed to respond to messages posted online. Because messages and posts to the Internet can remain online indefinitely and individuals can respond to these posts whenever they want, perhaps even days, weeks, or months after the post has been made; this lack of synchrony allows bullies the chance to post hurtful information at any time that they wish. Accessibility refers to the Internet users who have varied interests, age, and social backgrounds (Appel et al., 2014). Thus, in addition to anonymity, variation in age and differences in using the Internet may be affected by interests and social backgrounds, further compounding the problem of cyberbullying (Barr 2005).

Anonymity, asynchronicity, and accessibility can lead to adolescents feeling less conscious and apprehensive about their physical appearance, giving them greater confidence that they will not be discovered and punished for being cyberbullies (Beale & Hall 2007; Berson & Berson 2005, Slater & Tiggemann 2010). This is particularly the case for adolescent girls. That said, these three characteristics can also pose risks for adolescent development, such as increases in adolescents’ verbal aggression (Anderson & Bushman 2002). Cyberbullies have been found to be less inhibited in saying things to another person that they would never say face-to-face (Keith & Martin 2005; Sparling, 2004). Also, these three characteristics might allow easy access to sexual and/or violent content that is now readily accessible (Baumgartner, Valkenburg, & Peter 2010). In fact, Englander and Muldowney (2007) label cyberbullying as an “opportunistic offense,” because it results in harm without any physical interaction, may not require a lot of planning time, and the anonymity of the Internet reduces the chances that the cyberbully will be caught.

Cyberbullying As Covert Bullying

There are two broad types of how bullying is classified, and these types are based on how the bullying behavior is displayed. Researchers classify bullying according to whether it is overt or covert. Direct bullying refers to harassing others through direct (overt) physical or verbal attacks. Examples include hitting and pushing. Indirect bullying is also referred to as relational bullying. It is a covert form of bullying. Covert bullying creates harm by destroying the victim’s social relationships. Some examples of covert bullying include gossiping, spreading rumors, name calling, and excluding a person from their social group (Aricak 2008; Beran 2006; Bjorkqvist, Lagerspatz & Kaukiainen 1992; Coyne, Archer & Eslea 2006; Ma 2001).

Since cyberbullying is characterized by an absence of direct confrontation, it is best considered covert (indirect) bullying. If true, this tends to explain why girls, who might be less confrontational in face-to-face contexts, may be feel less inhibited when online, because they

can use the anonymity of the Internet to manipulate others (Ang & Goh 2010; Belsey 2004). Despite these dynamic features that distinguish cyberbullying from face-to-face, or traditional bullying, some researchers suggest that cyberbullying is not qualitatively different from traditional bullying. They argue that instead online harassment is merely an extension of bullying in face- to- face contexts (Li, 2006). For example, Hinduja and Patchin (2010) found that 65% of cyberbullying victims were also victims of traditional bullying. Seventy-seven percent of cyberbullies also reported being involved in traditional bullying.

ADOLESCENT-PARENT MICROSYSTEM

Adolescent Characteristics

Bullies, Victims and Bully-Victims

As indicated, defining cyberbullying is challenging due to difficulties in identifying repetitive behavior and in measuring power imbalances as they occur online. However, individuals who are involved in bullying are frequently divided into three distinct groups: bullies, victims, and bully-victims. Based on the responses of 3,767 middle school students in grades 6-8 in U.S. schools, Kowalski, Limber and Agatston (2008) found that 21% of students were identified as victims, 13% as bullies, 18% as bully-victims, and 48% as non-involved students. Bully-victims reported the highest percentages of simultaneously being a cybervictim (36%) and a cyberbully (23%).

Bullies are those who initiate aggressive behaviors with others. They are usually stronger than their peers and strive to achieve certain goals, such as control over others (Hazler, Carney, Green, Powell & Jolly 1997). Adolescent bullies have high emotionality and low self-control (Juvonen, Graham & Shuster 2003; Pellegrini et al., 1999). Traits, such as delinquency and aggressive behavior, are associated with being a bully in the traditional sense (Perren & Alsaker 2006). According to Piskin (2002), bullies come from families where physical punishment is used and there is little parental warmth and involvement. Victims are the opposite, they are the subject of the bullies' harassment, suffer from low self-esteem, and are usually physically weaker than their peers. Victims who are often targeted might be overweight, small in size, or have a learning disability (Willard 2005). Victims usually come from families where parents and family members might be overprotective (Piskin 2002). Being a traditional victim is associated with internalizing problems, such as depression and somatic symptoms (Arsenault et al., 2006). Traits associated with being a bully-victim are linked with both internalizing and externalizing problems (Haynie et al., 2001; Iverson, Broberg, Arvidsson & Gillberg 2005). Recently, there has been a surge in "cyberbullicides" - suicide that is directly or indirectly influenced by an individual's experiences with online aggression/bullying (Hinduja & Patchin 2010).

Victims might also attempt to retaliate through technology, because it is not as intimidating as face-to-face confrontations. Therefore, cyberbullying becomes a means of self-protection (Beran & Li 2007). Finally, bully-victims are those individuals who bully their peers and who are also bullied by their peers (Espelage & Swearer 2003). Children bullied in cyberspace may also bully others in cyberspace. Children bullied in school are also at risk of being bullied online. According to Patchin and Hinduja (2006), life in cyberspace is often intertwined with

life in the real world. Many adolescents spend their daytime hours with friends at school and public places. At night, they “see” their friends via chat, Facebook, and other social media sites. Whatever is discussed on these sites is talked about in the day, and vice versa. Technology has advanced so much that there is now no separation between the online and the offline worlds. According to Schneider et al. (2012), one third to more than three quarters of adolescents who are bullied online are also bullied while offline.

Individual Behaviors Characterizing Cyberbullying

The impact of cyberbullying may vary depending on the type of cyberbullying that the victim experiences (Calvete, Orve, Estevez, Villardon & Padilla 2010; Slonje et al., 2013). In interpreting the impact of cyberbullying, several major factors emerge as possible explanations for the impact of cyberbullying, including the social media involved and the specific actions or behaviors transmitted via social media. Some researchers have categorized cyberbullying as typically occurring in two primary social media venues--- the Internet and via cell phones (Ortega et al., 2009). The use of smart phones, however, makes it possible to send and receive e-mails on the cell phone and also to use the Internet beyond simply sending and receiving e-mails.

The technological transformation enabling the integrated use of Internet and cell phones has further increased attention to the specific actions or types of communication through which cyberbullying is perpetrated. Willard (2006) described eight categories: flaming (i.e., sending angry, rude, or vulgar messages to someone), online harassment (i.e., repeatedly sending angry, rude, or vulgar messages), denigration (i.e., put-downs, harmful, untrue, or cruel statements), cyber stalking (i.e., harassment that includes threats of harm or is highly intimidating), masquerading (i.e., pretending to be someone else and posting material that makes another person look bad), outing/trickery (i.e., engaging in tricks to get embarrassing information about a person and then making the information public), exclusion (i.e., intentionally excluding a person from a social group), and bombing (i.e., the cyberbully uses an automated program to cause the victim’s e-mail to fail and to block the victim’s e-mail account) (Bhat 2008; Burgess-Proctor, Patchin & Hinduja 2008).

Furthermore, all of these categories of communication are possible regardless of the medium through which cyberbullying occurs (e.g., through cell phone or Internet). To illustrate, Rivers and Noret (2010) described the contents of abusive text messages and e-mails. The ten major categories that they developed included: threat of physical violence, name calling, hate-related and abusive statements, death threats, description or portrayal of sexual acts, demands/instructions, and threats to the victim’s home or family and to their existing relationships. Similarly, Huang and Chou (2010) studied the types of cyberbullying behaviors across victims and bullies. For both victims and bullies, the most commonly reported behaviors involved threats and harassment, followed by making jokes, and then spreading rumors.

The face of cyberbullying has been changing. For example, smart phones are being used to check e-mail as well as to access the Internet. Social media, such as Facebook and Twitter, have gained popularity, allowing for communication involving the public posting of information such as photographs, with abundant opportunity for comments by others as well as anonymity. Texting via the Internet has emerged as another communication venue involving the need for brief statements, accompanied by the evolution of a new vocabulary. This new

terminology not only points to increased opportunities for cyberbullying but, as well, to increased need for responsible behavior and prevention strategies. Additional examples of such new terminology include “sexting” (circulation of sexual images without the victim’s consent), “trolling” (persistent abusive comments made online), and “griefing” (harassing someone in an online game). In short, the continued evolution of technological media has created opportunities for enhanced cyberbullying with devastating potential consequences.

Gender Differences

While some studies point to traditional or face-to-face bullying perpetrated primarily by men and boys (Beake & Scott 2001; Boutlon & Underwood 1992; Forero, McLellan, Rissel, & Baum 1999; Jolliffe & Farrington 2006; Sourander, Helstela, Helenius & Piha 2000), gender differences in cyberbullying are inconsistent. Some studies have found no gender differences between boys and girls, as perpetrator or as victim, while other evidence suggests that girls are more likely to be cybervictims and use psychological techniques of tormenting victims (Rivers & Noret, 2010). Other studies suggest that males engaged in cyberbullying more frequently than females (Calvete et al., 2010; Fanti et al., 2012; Harman, Hansen, Cochran and Lindsey, 2005; Li, 2006; Salmivalli and Poyhonen, 2012; Smith et al., 2008). However, while males reported more engagement in cyberbullying compared to females, females engaged in face-to-face indirect bullying and relational aggression more frequently (Anderson & Strum 2007; Crick & Grotpeter 1995; Hara 2002). One possible explanation for this is that girls tend to have more close-knit relationships and boys tend to socialize in larger groups with less sharing of personal details. In other studies, such as Dehue et al. (2008), boys (18.6%) were found to be more likely to be cyberbullies compared to girls (13.4%). Li (2006) studied 264 junior high school students in Canada and found that 55.6% of males and 54.5% of females were aware of cyberbullying. Twenty-five percent of males and 25.6% of females reported being victims of cyberbullying. Other researchers have found no gender differences between boys and girls in the rates of cyberbullying (Williams & Guerra 2009). The inconsistency of findings for gender differences in cyberbullying is largely the result of different samples and methodologies often using different types of cyberbullying.

Gender and Suicidal Ideation

Suicidal ideation is especially salient if social acceptance is vital to an adolescent’s identity and self-esteem. Being cyberbullied can have devastating effects on a victim’s psychological, emotional, and social well-being (Patchin & Hinduja 2006). In Roland’s (2002) study of 1,838 Norwegian eighth graders, boys who were the victims of cyberbullying had suicidal ideation 2.5 times more than non-bullied boys. Bullied girls had suicidal ideation that was 4.2 times more than non-bullied girls. The boy bullies suffered from suicidal ideation 3.8 times more than the non-bullies, and the girl bullies suffered from suicidal ideation 8 times more than the non-bullies. Cyberbullying makes the feeling of unhappiness even worse in the victim’s mind (Hinduja & Patchin 2009). Hinduja and Patchin (2009) found that youth who bullied others at age 8 were more likely to have suicidal thoughts at age 18 compared to non-bullies. There are many reasons why such negative outcomes befall bullies and their victims, including the

following: (a) the preservation of computer-based messages that are stored on web sites and search engines;(b) the ease and freedom through which hurtful statements can be made;(c) the difficulty identifying the bully, difficulty proving that cyberbullying occurred, and the challenge of determining appropriate punishment: (d) the possibility of cyberbullying extending beyond the classroom and school, minimizing the input of teachers; (e) the advancement of technology and its use bygrowing numbers of adolescents and young adults.

Age

Adolescence is a phase in life in which there is massive growth in social relationships outside of the immediate family (Giordano 2003). Interactions with their peers helps adolescents to refine their socio-emotional skills, to take different perspectives, and to consider intimate relationships (Crosnoe 2000; Rubin, Bukowski & Parker 1998). However, their expanding social circle also exposes them to risk, such as cyber bullying and harassment.

Cyberbullying, however, is not restricted by age and can occur from elementary school to the college years. For example, in a study of fifth, eighth, and eleventh graders, fifth graders were found to experience the least victimization rate (only 4.5% of their fifth grade sample were cyberbullied), eighth graders seemed to be at the peak of cyberbullying experiences (12.9%), and cyberbullying rates for eleventh graders dropped during high school (9.9%) (Williams and Guerra, 2007). Similarly, Tokunaga (2010) found that the greatest incidence of cyberbullying occurs around the seventh and eighth grades (around 13-15 years of age). Cyberbullying tends to decrease after late adolescence (Sevcikova & Smahel 2009).

PARENT CHARACTERISTICS/BEHAVIORS AND CYBERBULLYING

There is a lack of research on parents and how they influence their adolescents' risk of being involved in cyberbullying (Mesch 2009). There is evidence from some researchers that positive parent-child relationships may help to decrease the likelihood of cyberbullying (Ybarra & Mitchell 2004). This applies to both Asian and Western adolescent samples. In the field of digital media use, the most common question is the role that parents play in minimizing the risks that come with online technology. This is termed parental mediation, and the literature has focused on TV and its influence on children. According to Nathanson and Cantor (2000), there are two areas of parenting strategies: (a) active mediation, which involves talking with adolescents about the Internet, and (b) restrictive mediation, which involves setting rules and regulations. Of the two, Nathanson (1999; 2002) and Nathanson and Cantor (2000) have found that active mediation yields more positive results compared to regulating and restricting adolescents' media usage.

Parental Monitoring

Implications of parental monitoring are an important element cyberbullying. In a study of U.S. parents' and adolescents' online behaviors, adolescents whose parents monitored their

children's online behavior tended to be more cautious in disclosing such personal identifying information as their name or e-mail address (Rosen, 2007). Other evidence suggests that giving out personal information, visiting inappropriate sites, and total amount of time spent online was lower for the adolescents whose parents had specific rules that limited their online activities (Beebe, Asche and Harrison, 2004).

Due to the anonymity and accessibility of the Internet, however, parents' restriction of their children's media usage has been shown to be ineffective. This is because Internet activities might occur outside of parents' control. Also, young people and parents relate differently to technology (Keith & Belsey 2004; Martin 2005). That is, adults view computers as practical tools, whereas children and adolescents view the Internet and technology as a "lifeline" to their peers (i-SAFE 2004; Keith & Martin 2005). Sites, such as Facebook and chat rooms, might be considered "safe" but they can contain very inappropriate material (Mesch 2009; Shin & Huh 2011). Communication between parents and their adolescents can facilitate awareness of cyberbullying and possible resources to cope with these Internet stressors (Appel, Holtz, Stiglauer & Batinic 2012). For example, in a study of 363 secondary school German adolescents, the quality of Internet-related communication with their parents mattered (Appel et al., 2014). Adolescents who did not have or engage in this type of communication had an increase in verbal aggression over a six-month period. Those who had high levels of communication had the reverse relationship. The reluctance of students to disclose cyberbullying to their parents is because some parents view physical bullying as more serious and harmful than verbal and indirect bullying and are less likely to intervene in cyberbullying cases (Aftab 2005; Barr 2005; Dehue Bolman & Vollink 2008).

Parental Communication

In general most adolescents do not talk to their parents about their online experiences, especially those that are stressful or annoying (Appel et al., 2014). Nine out of ten adolescents aged 12-17 years were found to not tell their parents about cyberbullying (Juvonen & Gross 2008), even in cases where the cyberbullying causes severe emotional distress. In Patchin and Hinduja's (2006) study, 56.6% of their sample responded to cyberbullying by telling an online friend. Even fewer (19.5%) told their parents and only 16.8% reported telling a sibling. In the popular press, a United Press International (UPI) study found that fewer than 10% of victims turned to their parents for help (UPI, 2008). In a similar finding, a study of 38 fifth through eighth graders found that children did not tell parents or other adults about their cyberbullying experiences because they felt that adults would not be able to identify the bully or to find evidence that cyberbullying occurred (Mishna, Saini, and Solomon, 2009). Other reasons included wanting to be independent, the fear that reporting the cyberbullying would make the problem worse, or the adult would tell the victim to ignore it (Mishna et al., 2009). Similar findings can be found with Li (2006), who found that only 30% of adolescents disclosed their cyberbullying experience to an adult. As in the case of traditional bullying, the rates of disclosing to an adult are minimal.

Furthermore, there is evidence that adult monitoring of adolescent Internet usage is a relatively infrequent parent practice (Berson and Berson 2005; Ybarra and Mitchell 2004). This is likely a significant contributor to the at-risk behavior among adolescents. For example, Ybarra and Mitchell (2004) found that 30% of adolescents used the Internet for three or more

hours per day. More than half of these adolescents reported poor parental monitoring, 7% reported that their parents knew where they were online, and 9% reported that their parents rarely knew who they were spending their time with outside of the home (Ybarra & Mitchell 2004). Interestingly, Odendaal, Malcolm, Savahl, and September (2006), in their study of 23 tenth graders between the ages of 14 to 16 years old, found that most of these students were not monitored by adults. Despite this, victims tend to trust their parents over school officials to help them find a solution to being cyberbullied.

Other factors that affect parent-adolescent communication on cyberbullying and other matters of adolescence include age, gender, and cultural experience. Both age and gender have already been discussed with reference to other aspects of cyberbullying, including prevalence and correlates (see above). That said, as students get older, they are less likely to confide in their parents or guardians about being cyberbullied (Cassidy, Jackson & Brown 2009). With reference to gender and cyberbullying victimization, Li (2006) found that female cyberbully victims were more likely to tell adults (including parents) if they had been cyberbullied. One possible explanation is that men/boys regard asking for help as putting themselves in a “one down” position (Tannen 1994).

With reference to cultural factors in cyberbullying communication, Li (2006) sampled 157 Canadian students and 202 Chinese students from China. She found that Chinese students were more likely than their Canadian counterparts to believe that adults in schools will try to fight cyberbullying. Also, Chinese students were more likely to tell adults about cyberbullying incidents. Cultural differences between China and Canada could account for these differences, in particular China’s emphasis on Confucianism, which posits that children should show respect to authority, including parents and teachers (Cole et al., 1997).

THE ADOLESCENT-PARENT RELATIONSHIP: CHARACTERISTICS AND RELATIONSHIP QUALITY

The past three decades has seen unprecedented interest in understanding the relationship between the socio-familial environment and childhood aggression. Few studies, however, have investigated the parent-child context as a proximal risk factor for the onset of bullying behaviors. The few studies that do tend to implicate family violence (Farrington 1993), specific parenting styles (Baldry & Farrington 2000), and the lack of parental monitoring (Roberts & Coursol 1996; Low & Espelage 2013) in the etiology of face-to-face and online victimization. These studies have emphasized the family’s role in modeling aggressive behaviors either directly, for example through family violence (Shields & Cicchetti 2001) and parental conflict (Baldry 2003), or indirectly by being part of a causal chain of risk factors for bullying perpetration or victimization. This includes things such as living with a depressed parent, low levels of parental attachment, and the lack of cognitive stimulation (Beran & Violato 2004; Zimmerman, Glew, et al., 2005).

SOCIAL LEARNING AND ECOLOGICAL PERSPECTIVES

According to social learning theory and social interaction learning theory, maladaptive and aggressive social interactions with peers originate in impaired and conflictual family dynamics (Patterson 1982; Patterson, Dishion & Bank 1984). Compared to children growing up in non-violent households, children exposed to violence are developmentally disadvantaged due to recurring health problems (Bowes et al., 2009) and posttraumatic stress (Kilpatrick & Williams 1998). The cumulative impact of violence exposure coupled with complex stressors and comorbidities that often accompany violence has been linked to the development of both internalizing and externalizing behaviors in children. Chronic exposure often culminates in what has been coined the ‘cycle of violence’ (Holt, Buckley & Whelan 2008). Generally speaking, face-to-face bullying and cyberbullying behaviors are consistent with social learning theory and the role of maladaptive socialization within the family context in promoting such behavior. The social interactions in the home are a critical source of origination for diverse forms of aggressive behavior (Low & Espelage 2013), including diverse forms of face-to-face and online abuse. Children living in families characterized by deficient parents are “mis-socialized” into acting aggressively either directly or indirectly. While few in number, studies have found a strong, positive relationship between domestic violence and bullying, thereby corroborating previous research suggesting that children who are exposed to family violence engage in higher levels of both generalized aggression and bullying (Bauer et al., 2006). In one study, for example, exposed youth were nearly three times more likely to partake in bullying and/or threatening other students at school and more than twice as likely to spread gossip or exclude others from participating in group activities (Baldry 2003).

Another type of family violence, abuse directed towards the child himself or herself, shows strong associations to online aggression. Children who witness domestic violence are more likely to be involved in bullying and/or victimization, even after controlling for the individual-level characteristics of age, gender, and other childhood adversities, such as the presence of child abuse or neglect. Child maltreatment has been shown to operate directly and indirectly to increase the likelihood of being a victim or perpetrator of bullying. Child victims of physical and sexual abuse, for example, have been shown to be more likely to engage in bullying or be victimized by peers (Bowes et al., 2009; Low & Espelage 2013). Being a victim of abuse may also be an intervening variable that manifests itself through internalizing behaviors in the causal chain from child mistreatment to aggression. For example, both childhood maltreatment and domestic violence have associations with childhood depression and anxiety, which in turn is a risk factor for bully victimization. It is possible, then, that a child's individual traits act to confound the direct relation between socio-familial characteristics and the likelihood of being involved in bullying, but future research must be done to parse out the relative influences of each.

Drawing on an ecological perspective, Osofsky (2003) concludes that violence exposure is a prerequisite risk for future aggression but children must also come to view aggression as functional in their relationships and subsequently believe violence is an acceptable method of conflict resolution (Holt, Buckley & Whelan 2008). Children exposed to violence in the home often learn that violence is a normal way to be treated or respond to conflict and in turn become aggressive toward peers. In this regard, domestic violence is relevant for explaining aggressive behavior as learned phenomena whereby poor social skills moderate the relationship between

violence exposure in the family and involvement in bullying. According to Lundy and Grossman (2005), the development and preservation of friendships at a critical developmental period is compromised by poorly developed social skills. They may either pick up on and react to aggressive cues in their interactions with other children and consequently be at risk of bullying or tune out from such cues and be at increased risk of being bullied (Bauer et al., 2006; Cunningham & Baker, 2004). One-third of Lundy and Grossman's (2005) sample of 4,636 children who were exposed to domestic violence were described as frequently aggressive, and one-fifth had difficulties adhering to the rules of the school, with the acting out, peer difficulties, sadness, and depression, frequently bringing them to the attention of the teachers. Deficient parenting impairs a child's social competence and consequently the ability to develop positive friendships, whereas parents who are involved in their children's lives and supervise them are instrumental in reducing aggressive behavior both within and outside of the family (Duman & Margolin 2007; Knutson, DeGarmo & Reid 2004; Mazefsky & Farell 2005).

EMOTIONAL DYSREGULATION AND CHILD EXPOSURE TO FAMILY VIOLENCE

On the basis of social learning theory and emotional dysregulation, children who are exposed to violence in the home are more likely to develop negative relationship patterns and model them with peers (Low & Espelage 2013). Concurring with this hypothesis, Graham-Bermann and Brescoll's (2000) research with 221 children between 6 and 12 years of age and their mothers found a direct relationship between the level of physical and emotional abuse of mothers and children's belief systems regarding the acceptability of violence in family interactions. Reflecting on family systems theory, these authors surmise that children in abusive families have internalized belief systems that are conditioned through acts of physical abuse. Taken together, these findings suggest that perceived parenting behaviors are in fact related to adolescents' engagement in cyberbullying. An important qualification, however, is that family context is neither monolithic nor does it exist in a cultural vacuum. A family's cultural values and belief systems underlie their social contexts and will govern online social interactions in much the same way they do face-to-face communications (Shapka & Law 2013).

While highly variable, a simplified way of understanding parenting styles is to view them in two dimensions: (a) how responsive are parents to the behavior of their children, and (b) how demanding are parents in limiting their bad behavior. The former dimension is characterized by warmth, support, acceptance, and affection, while the second refers to supervision, control, and monitoring (Baumrind 1991; Spera 2005), and both dimensions include aspects of the child-parent relationship that are predictive of both face-to-face bullying (Baldry & Farrington 1998, Rigby 1996; Smith & Myron-Wilson 1998) and cyberbullying behaviors above and beyond violence exposure and parental conflict. Parents who interact with their children in a hostile, cold, and indifferent manner encourage their children to interact with others in a similar way, which affects the socialization of their children and may increase a child's likelihood of becoming a bully (Pontzer 2010). In an online environment, parenting styles are particularly important (Law et al., 2010). In this vein, research has found that children who cyberbully experience limited parental monitoring, stronger parental discipline, and a weaker emotional bond with their parents than children who do not cyberbully (Ybarra & Mitchell 2004; Wang,

Ianotti & Nansel 2009; Wong 2010). For youths who are involved in traditional bullying and in cyberbullying, bullies, victims, and bully-victims report less responsiveness and demanding behaviors by parents than non-involved youths. Research findings have consistently found a negative association between authoritative parenting styles and both online and face-to-face bullying; simply put, unresponsive parents have children who exhibited higher levels of cyberbullying perpetration and cyberbullying victimization.

Due to parents' lack of sophistication or knowledge about technology, some have speculated that parents may feel uneasy about their adolescents' proclivity to engage in online activities (Livingstone 2002; Stanaland et al., 2009). Consequently, greater efforts to monitor and control their children's online activities (Smetana 2000) are frequently implemented. Children of parents with inadequate supervision, inconsistent discipline and lack affection and support are more likely to have children who engage in bullying behaviors. In contrast, when parenting is characterized as warm and consistent children display much lower levels of antisociality (Bacchini, Miranda & Affuso 2011; Brown, Arnold, Dobbs & Doctoroff 2007; Demetriou & Christodoulides, 2011; Getachew & Sintayehu, 2007; Knutson et al., 2004; Luyckx et al., 2011). However, Stattin and Kerr (2000) found that controlling and monitoring adolescents' Internet use was not associated with fewer reported incidences of cyberbullying. Similarly, Mesch (2009) found that parental use of restrictive mediation (limiting and controlling adolescent's online activities) was not effective for reducing reports of cyberbullying, but those that engaged in evaluative mediation (open discussion about the internet and the co-creation of rules) had children with less risk for exposure to cyberbullying. Adolescents who feel supported (Park, Kim & Cho 2008) and comfortable disclosing their online experiences to their parents were less likely to report engaging in online risk behaviors (Law et al. 2010; Shapka 2011). These findings are consistent with a larger body of work on the parental mediation of children's online behavior that was discussed above or the activities carried out by parents to protect their children from exposure to online dangers (Dehue et al., 2012). Research has shown that when parents closely monitor their children's online activities, they are less likely to disclose personal information, less likely to seek out inappropriate sites, and less likely to conduct chat conversations with strangers. Researchers posit that when parents do not engage in these practices, they indirectly promote aggression and victimization by dampening the social competencies of their children (Duman & Margolin 2007; Knutson et al., 2004; Mazefsky & Farell 2005; Pontzer 2010). Thus, it has been suggested that the lack of responsiveness and demanding behaviors of parents as role models impairs the social competence of both bullies and victims (Perren & Hornung 2005; Stevens et al., 2002).

This is especially true in the case of cyberbullying since peers and teachers, as possible role models, are frequently unaware that a child is a cyberbully or is being cyberbullied (Aricak et al., 2008; Dehue et al., 2008).

SOCIALIZATION AND PARENTING STYLES

The broader familial context, including the role of socialization and parenting styles, needs further investigation, given its relative dearth in the bullying literature. According to Low & Espelage (2013), the field would benefit from a deeper unraveling of family conflict in order to understand the potential additive and synergistic role of violence and conflict in the family.

Nevertheless, the current research suggests several points of prevention and intervention of aggressive online behaviors. First, a holistic and ecological approach would integrate family and individual levels, as well as negative outcomes of family violence and poor parental practices to better unravel their role in developing social competencies (e.g., positive assertiveness, empathy) and emotion management. These programs should also consider cultural underpinnings associated with parenting styles and in particular the cultural values that create vulnerability to cyberbully victimization or perpetration. This includes a consideration of gender and race/ethnicity since subgroup differences exist with respect to both family violence and parental treatment of children.

THE FAMILY CONTEXT AND CONTEXTS BEYOND THE FOCAL ADOLESCENT-PARENT RELATIONSHIP: IMPLICATIONS FOR POLICY AND INTERVENTION

An effective adolescent parent relationship is both a potential venue for reducing cyberbullying, a powerful asset for promoting positive adolescent development and a basis for preventing or reducing cyberbullying. In fact, it has become increasingly apparent that many existing programs for reducing standard bullying and quite possibly cyberbullying, end up emphasizing dimensions of positive youth development, including the enhancement of adaptive individual characteristics and individual connection to positive family and community resources.

This points to the importance of an ecological perspective to prevention and reduction of cyberbullying, directed at the multiple ecological contexts of cyberbullying, including the family and contexts beyond the family (including the community/ neighborhood or the school). Building on existing models of traditional or face-to-face bullying emphasizing the bi-focal bully-victim relationship as the basic microsystem context of bullying (Barboza et al., 2009; Espelage & Swearer 2011; Veenstra et al., 2007), an enhanced ecological approach to policy and intervention, for both in traditional bullying and cyberbullying, includes a Positive Youth Development (PYD) framework (Lerner et al., 2005). Specifically, an emphasis on adolescent internal assets (e.g., competence, caring, connection) and external assets (e.g., family, school, community) in honing and shaping internal assets essential for Positive Youth Development (PYD) are, in turn, essential for preventing/reducing both traditional and cyberbullying as well (Theokas & Lerner 2006).

THE ECOLOGY OF BULLYING AND POSITIVE YOUTH DEVELOPMENT (PYD)

The Ecology of Bullying

Using the bully-victim relationship as the focal context of both face-to-face bullying and cyberbullying, ecological models have been developed which provide a basis for understanding the dynamic character of bullying as a contextual phenomenon (Barboza et al., 2009; Espelage & Swearer 2011; Veenstra et al., 2007). Barboza et al. (2009) examined risk factors of bullying

for a sample of adolescents, ages 11-14 ($N = 9,816$), from *Health Behavior in School Children: WHO Cross National Survey*. The study modeled the relationship between bullying and media effects, peer relationships, family support networks, and self-efficacy, supporting the significant role played by contexts within and beyond the bully-victim relationship. Many of these individual characteristics and contextual supports, including the family, are associated with constructive PYD positive youth developmental outcomes, which, in turn, provided evidence-based support for some existing and future directions in prevention, remediation, and policies for both traditional bullying and cyberbullying.

Incorporating Positive Youth Development (PYD)

The incorporation of positive youth development (PYD) is particularly relevant as it underlies the internal and external assets of PYD which are the very goals of many existing and effective bullying and cyberbullying programs. From a PYD framework, positive individual assets or adaptive individual characteristics are frequently described as the 5C's (Benson, Mannes, Pittman & Ferher 2004). These internal assets include the following (5C's): *competence* (intellectual ability/social behavioral skills), *connection* (positive bonds with people and institutions), *character* (integrity and moral centeredness), *confidence* (positive self-regard, self-efficacy, courage), and *caring/compassion* (empathy, sense of social justice). When all 5Cs are present, *contribution to civil society* (i.e., youth actions in support of social institutions and other individuals) is made more likely (Lerner et al., 2000). These internal assets are made possible by, and occur in the context of, external assets in the form of *support* (e.g., positive family support/communication, other adult relationships, a caring community, positive/caring school climate), *empowerment* (e.g., community values youths as resources), *clear expectations/ boundaries communicated in context* (e.g., family has clear rules, schools communicate rules and expectations, positive peer influences, available adult role models), and *constructive use of time* (youth programs, creative activities).

While most research on bullying has focused on the negative indicators and outcomes of adolescent bullies and victims, more recent studies have taken a strength-based approach to bullies and victims of bullying (Hilliard, Bowers, Greenman, Hershberg, Geldhof, Glickman, Lerner & Lerner 2014; Ma, Phelps, Lerner & Lerner 2009a; Ma, Phelps, Lerner & Lerner 2009b). For example research on moral virtues compared the trajectories of moral character (e.g., doing the right thing, staying out of trouble), performance character (e.g., persistence, self-discipline, self-regulation), and civic character (e.g., leadership, helping, service) by bullying status (e.g., bullies, victims, and adolescents not involved in bullying) from middle school to high school (Hilliard et al., 2014). Adolescents who reported being bullies and being victims had lower levels of moral and civic character while bullies reported higher levels of performance than youths who did not experience bullying. Although there was individual variability in these character virtue trajectories, the general study findings suggest potential opportunities for maximizing on character virtues for bullies and victims at, or even earlier than, the 7th grade level and, including the potential redirection of increased bully performance character in positive and more constructive directions.

Other studies focusing on PYD are also illustrative of opportunities for tapping individual internal assets and community and family external assets in the social ecology of youth involved in bullying. Ma et al. (2009a) focused on the interplay of expectations for school

success, and they found that engagement in school encouraged academic competence in youth Grades 5 - 7. In a related study, Ma and colleagues (2009b) found that both teacher and parent support independently predicted the PYD individual asset of academic competence for both bullies and victims in grades 5th through 7th. It is important to keep in mind the importance of individual differences in trajectory patterns such that the development of positive characteristics does not automatically imply that negative and problematic behaviors such as bullying will be eliminated (Hilliard et al., 2014). This means that strength-based efforts to diminish cyberbullying, specifically the promotion of PYD, needs to be included, in a comprehensive effort, with programs designed to specifically eliminate or prevent cyberbullying (e.g., teaching about cyber security).

THE ROLE OF FAMILY IN CYBERBULLYING INTERVENTIONS

The nature and quality of the parent-adolescent relationship provides a critical ecological context for understanding both the dynamics of cyberbullying victimization and, in turn, for developing effective intervention and prevention strategies. However, there is limited research on the critical details of this vital role, particularly in adolescent social media involvement and effective parental responses. There is some agreement that involving families as either the primary adolescent asset in an intervention or as part of a comprehensive community effort including community/neighborhood or school resources may be useful in reducing cyberbullying. While such programs appear to have had some level of success in combating cyberbullying, it is not clear exactly how the dynamics of the adolescent-parent relationship create outcomes which may successfully reduce cyber bullying.

A recent investigation using data from a Pew study which involved telephone interviews of a representative sample of adolescents aged 12-17 and their parents examined the relationship of youths' self-reported bullying victimization with parental strategies for preventing adolescent online victimization (Schiamberg & Barboza 2014). The analytical sample for the study included those adolescents, and their parents, who reported cyberbullying victimization, via a social media website or text message in the past 12 months ($n = 509$). Results of the study addressed patterns of adolescent-parent communication, parental knowledge and monitoring of youth online activities, and adolescent knowledge of their parents' monitoring of their online behavior on cyberbullying victimization. The findings revealed that (a) youth whose parents reported monitoring their child's use of the Internet by blocking or filtering websites were significantly less likely to be victims of cyberbullying, (b) youth who perceived that their parents used the internet to check websites they visited were also less likely to be bullied, and (c) adolescents whose parents reported talking to them about internet safety were significantly less likely to be cyber bullied. Other forms of communication and monitoring (e.g., suggesting ways to behave, discussing online activities, checking online profiles, or checking to see what information is available) were unrelated to cyberbully victimization.

These results suggest the complex nature of the interaction between the parent-adolescent relationship and cyberbullying victimization. While adolescent-parent communication about online activities is essential, the form of the communication is what really matters. The most effective form of communication is about being safe *in general*. While parental monitoring is

a protective factor, children's perception that controls are in place (i.e., by blocking or checking websites) is also effective at minimizing the likelihood of cyberbully victimization. While important, an awareness of adolescent online activities is not as effective as parents' knowledge and use of the Internet. Preventing cyberbully victimization requires that parents themselves have knowledge about the types of activities their children are doing online.

PYD AFTER-SCHOOL CYBERBULLYING INTERVENTIONS: ACROSS FAMILY, COMMUNITY AND SCHOOL

While bullying of children and youth is a serious social problem, attempts to address the problem have tended to focus almost entirely on the role of the school as both a focal point for bullying relationships and for intervening in those relationships. Although of considerable importance in providing a positive environment for adolescent development and support, a full understanding of the complexity of bullying involves the appreciation of contexts beyond the school such as community and family as places for bully-victim relationships as well as for interventions designed to prevent bullying. In fact, there is good reason to believe that many youth can be served effectively in after school programs, perhaps in conjunction with school programs.

While schools represent an obvious location for some bullying events, it is important to recognize the role of out-of-school organizations and programs in reducing and preventing face-to-face bullying and cyberbullying. Working in collaboration with formal schools, out-of-school programs represent a significant opportunity for many youth to reach out to trained and caring adults to build positive youth assets (e.g., individual characteristics and community connections for preventing and reducing bullying) (Barboza et al., 2009; Durlak, Weissberg & Pachan 2010).

According to the 2010 Youth Risk Behavior Survey, nearly 23 percent of public high school students in Michigan reported being bullied at school one or more times during the previous 12 months (CDC, 2011). While these statistics reflect school-based bullying experiences, peer-perpetrated events very often occur outside school environments, particularly when accounting for the presence of electronic aggression or cyberbullying behaviors (Turner, Findelhor, Hamby, Shattuck & Ormrod 2011). While concerns about the prevalence and consequences of bullying are valid, an exclusive focus on a deficit perspective, focusing on bullying as a set of problem behaviors to be eliminated and prevented, may be necessary but is not sufficient. Such efforts often frame the issue as a generic youth problem, rather than examining the complex issues surrounding both traditional and cyberbullying through the ecological frame of the intersection of social contexts and youth development. In short this means viewing the solution to the problem of both traditional and cyberbullying as the connection of bullying programs to the internal and external assets of of Positive Youth development (PYD)..

Be SAFE: Addressing Bullying Across Community Settings is an after school program based on Positive Youth Development (PYD), reflecting an ecological, community-wide approach to addressing the complex issues of bullying (Olsen and Pace, MSU Extension and Outreach, 2012). The initiative improves knowledge about healthy and unhealthy relationships and settings while building skills and strategies for addressing bullying behaviors. Be SAFE

involves after school partnerships among adolescents, educators, volunteers, families, and other community members who are involved in a variety of opportunities through the *Be SAFE* curriculum for early adolescents, adult leadership development, parent/caregiver education, collaborations with schools, and other youth and family organizations. Preliminary focus group evaluations of the program (involving youths and cooperating adults) on a variety of dimensions related to bullying and cyberbullying indicated the emergence of successful group processes in both developing specific steps for reducing/preventing cyberbullying (e.g., ensuring cyber safety and awareness among participating parents and youth) and specific collaborations to promote PYD.

Chapter 11

SOCIAL-ECOLOGICAL PERSPECTIVE: POWER OF PEER RELATIONS IN DETERMINING CYBER-BYSTANDER BEHAVIOR

Deborah Price* and Deborah Green

University of South Australia, School of Education
Adelaide, Australia

INTRODUCTION

Social networking sites, such as Facebook, have been described as a “full-fledged friendship lifeline” for young people (Bevan, Pfyl & Barclay, 2012, p. 1458) as they provide a forum to form, maintain, and end friendships (Lodge & Frydenberg, 2007; Sibona & Walczak, 2011). These sites are defined as web-based services that allow individuals to: (a) construct a public or semi-public profile within a bounded system, (b) articulate a list of other users with whom they share a connection, and (c) view and traverse their list of connections and those made by others within the system (Boyd & Ellison, 2007). Across a range of social media platforms, young people around the globe are engaging regularly in online situations similar to the Facebook ‘defriending’ scenario described in Figure 1 (Madden, 2012).

Online social networking sites provide opportunities to add people as friends or innocently or maliciously provide power to remove or delete the person. This process is known as ‘defriending’ in the United Kingdom or ‘unfriending’ in the United States (Bishop, 2012). In these situations, various roles are engaged, including the bully, the victim and, of particular interest in this chapter, the cyber-bystander. Bystanders act in a number of ways: some defend the victim, others reinforce the bully, and many remain uninvolved (Salmivalli, Lagerspetz, Björkqvist, Osterman, & Kaukiuanen, 1996). The rapid emergence and popularity of digital technologies encompasses ever changing social media platforms that come in and out of favor with young people on an ongoing basis. They provide instant visual and audio communication with individuals, groups, and communities, which can include personal friends, family, and

* Corresponding Author’s Email: Debbie.price@unisa.edu.au

complete strangers around the world. Once any form of communication is posted, its dissemination can be far reaching and instantly irretrievable. For many, this can have long lasting positive and negative effects. Unfortunately, whilst social media has provided a positive innovation to socialization, business, marketing, and communication, it has prompted the emergence of the phenomenon of cyber-bullying. Extensive research has endeavored to analyze the roles of bullies and victims, and in face-to-face bullying, the role of the bystander has gained focus. Given the large population engaging online in social media platforms, less is known about the cyber-bystander. Who are they? What do they observe or hear? How do they act? What factors influence why they act, how they act, or choose not to react?

Two friends, a girl, Tayla, and, a boy, Sam, are on Facebook chatting. Tayla claims that Katie has been mean to her in class.

Tayla: *OMG did you hear what she said to me 2day?*

Sam: *No like what?*

Tayla: *She was like "if you did ur homework wen u were supposed 2 u'd know the answers in class". She is such a bitch... who the hell asked her.*

As a result, Sam suggests that she should pick on Katie by trashing her Facebook page or posting a gross picture of her. Together they decide to ask all the boys and girls they know to "defriend her". They hoped that Katie would turn up to school the next day with no friends and then everyone would laugh at her for being a 'loser' and she 'will totally lose it'.

Tayla then emails everyone saying:

Hey guys.

So... Sam and I have been talking & we have a heaps funny job 4 u all. Some of u may know that Katie was a total bitch in class 2day & we want 2 get her back 4 being such a mole. I know u guys r just as sick of her bossy, loser ways as I am, so this is wat u need to do.

Delete Katie off ur Facebook account...like... 'defriend' her completely. She won't know till she rocks up 2mrw & finds she has no friends on FB & no friends in class either! Lmao!!

It'll be hilarious & she'll totally lose her shit, which is exactly what she deserves after being such a cow.

Seeya 2mrw...should be awesome.

Bec (Katie's supporter) starts to join in by emailing her support to Tayla; however, before sending her response she thinks better of it. Instead she decides to alert Katie about what is going on.

In relation to this scenario, consider the following:

- What roles do Tayla, Sam, Bec, Katie and the peer group play?
- Who are the bystanders in this situation and how can they help?
- What makes a cyber-bystander help?
- How would you act in a similar situation?
- What might make someone like Bec decide to support Katie?
- What might make others decide to 'defriend' Katie and support Tayla?
- How do social-ecological factors influence cyber-bystander behaviors?

Figure 1. Facebook 'Defriending'.

In this chapter we explore the power of peer relationships as a significant factor in determining cyber-bystander behavior. We particularly focus on factors including: belonging, acceptance, hierarchical power, group norms, agency, social conventions, and friendships.

These elements will be further analyzed in relation to broader, bi-directional interrelations and influences across social-ecological systems (Bronfenbrenner, 1979). Engaging the voice of the young people who are active users of social media and can share first-hand knowledge and perspectives is central to understanding cyber-bystander behaviors. Although it is recognized that Facebook will be replaced by other exciting new iterations of online interaction, the key message of this chapter surrounding the power of peer relations in determining cyber-bystander behavior will have far reaching applications for future social media platforms. We begin by understanding the nature of peer relations, in particular the notion of power.

Power of Peers

The fundamental need to belong can shape and influence behavior (Baumeister & Leary, 1995; Osterman, 2000). Belonging to one's peer group plays an important role in young people's academic achievement and more importantly their wellbeing (Dreikers as cited in Charles, 2002). Gaining and maintaining peer acceptance often motivates the way young people act whereby they establish group norms which determine what is considered acceptable by the peer group. These factors subsequently influence bystander behavior.

Peers play a powerful role in young people's lives, but who are they? They are individuals who share similarities, such as age, interests, school, workplace, etc. Although peers can be friends, this is not always the case. Despite this, peers play a significant role in the way that individuals and groups act and behave. Social behavior is never a function of the individual alone, and therefore one often acts differently depending on the company they are in and broader social-ecological influences. As you read this chapter, consider your own perspective and the role that your peers have played in supporting or influencing your behavior.

Early in life, within the microsystem of the home environment (Bronfenbrenner, 1979), families provide the primary source of social education. However, as young people mature there is a subtle, yet developmentally significant shift toward peers (Rubin, Bukowski & Laursen, 2009). This results in the formation of a separate friendship/peer group microsystem. When seeking understanding, emotional support, companionship and approval, adolescents consistently value friends more highly than parents, highlighting the importance they place on these relationships. At this time, learning occurs from peers, family/caregivers, educators, and significant adults across numerous ecological systems. At the mesosystem level, interactions across the microsystems of home, school, and friendship/peer groups provide complex influences on a young person's development and behavior (Bronfenbrenner & Morris, 1998). Within the friendship/peer group microsystem, the power of peers in providing acceptance or rejection influences and shapes young people's behavior. Such experiences and interactions teach lessons about what is and is not acceptable. The establishment and reinforcement of group norms within this microsystem influences bystander behavior, which may subsequently reinforce or inhibit bullying. Of note, it has been found that when peers/bystanders intervene in bullying situations, their actions have been successful in the majority of instances (Rigby & Johnson, 2006). Given such power, peers, regardless of whether bullying occurs face-to-face or online, seemingly hold the key to reducing bullying.

To explore cyber-bullying and the role of the bystander, one needs to draw on an understanding of bullying in any context. Bullies are often motivated by status and dominance, supporting the argument that peer groups are powerful in determining who has the power within

the group (Atlas & Pepler, 1998; Hawkins, Pepler & Craig, 2001; Long & Pellegrini, 2003; Salmivalli, 2010; Sijtsema, Veenstra, Lindenberg, & Salmivalli, 2009; Sutton, Smith & Sweetenham, 1999). In relation to the microsystem of a social media platform, such as Facebook, cyber-bystanders observe and possibly interact to enhance the bully's social status by spreading the word among others that the bully is powerful. From the bully's perspective this reputation, as perceived by others, may be self-fulfilling (DeRosier, Cillessen, Coie & Dodge, 1994; Green, 2014), while for bystanders it may prevent them intervening as they '*wouldn't want to become another target*'. The actions, or lack of actions of members in the peer group, the bystanders, can be seen as supportive, thus reinforcing the bully's behavior and increasing the likelihood of the behavior being repeated (Lagerspetz, Björkqvist, Berts & King, 1982; Pikas, 1975; Whitney & Smith, 1993).

Figure 2. Nine year old girl's perception of bullying (Green, 2014).

As depicted in Figure 2, bullying is not isolated to the bully and victim, others are present in the majority of instances (Atlas & Pepler, 1998; Craig, Pepler & Atlas, 2000). Peers play either active or non-active roles with some indirectly or directly supporting the victim or the bully, while others remain uninvolved. To further extrapolate this, Salmivalli and her colleagues (1996) identified various participant roles: the *bully* who instigates the bullying behavior; the *follower* who joins in after the bullying has begun; the *reinforcer* who is not actively involved but reinforces by watching, laughing, and encouraging the behavior; the *outsider* who is completely uninvolved; the *defender* who helps the victim; and the *victim* who is the target of the bullying. These roles provide members of the peer group with a sense of belonging and are often influenced by an individual's emotions, attitudes and motivations. By means of definition, the term 'bystander' suggests that these individuals 'stand by', yet their presence determines

whether bullying continues or not (Price et al., 2014). Empowering bystanders to act has been a major focus not only in education but society in general. Bystanders are more likely to intervene if they have done so before, are pro-victim and hold the belief that others, particularly their friends, would expect them to intervene (McLaughlin, Arnold & Boyd, 2005). So, in the context of cyber-bullying and the scenario provided at the outset of this chapter (Figure 1), how powerful are peers in determining cyber-bystander behaviors and what are the social-ecological influences?

THE PRESENT STUDY

Facebook ‘Defriending’: The Power of Peer Relations in Determining Cyber-Bystander Behavior

‘Defriending’ can have a significant negative impact on victims, particularly if they spend considerable time on Facebook and/or are psychologically invested in it (Bevan, Pfyl & Barclay, 2012). As illustrated in the scenario presented at the beginning of this chapter, ‘defriending’ often occurs among girls and is typically instigated by an offline event, such as Katie’s in-class comment to Tayla (Bevan, Pfyl & Barclay, 2012; Keith & Martin, 2005; Lodge & Frydenberg, 2005). However, boys are not immune to such actions as they too are susceptible to peer influences. To further understand the power of peer relations in determining cyber-bystander behavior, we draw on the voice of 961 students from a metropolitan Australian secondary school, Years 8-12 (mean age of 15 years) and their participation in a University of South Australia research project titled, *Cyber-bystanders: the role of the bystander in cyberspace and cyber-bullying in an Australian context* (Spears, Johnson, Scrimgeour, Geer, Price, & Green, 2010). These young people were asked to respond online to questions after viewing a digital animation of a typical cyber-bullying scenario. This scenario comprised of the Facebook ‘defriending’ situation outlined at the beginning of this chapter. The animation depicted a Facebook chatroom, and displayed text on a computer screen in the same way that it appears in a real chatroom. To help understand what was being typed on the screen, a narrator read the exchange between the parties. Participants’ responses reflected the power of peer relations on cyber-bystander behaviors across ecological influences: individual (e.g., decision making, attitudes, and beliefs), peer group (e.g., relationships, norms, and acceptance), school (e.g., class and whole school programs, values, and teacher perspectives), home (e.g., family values, digital divide), community (e.g., attitudes, bullying initiatives and projects), policies and legislation (e.g., National Safe School Framework, cyber laws), as well as time critical factors (e.g., global events, internet speed and personal/family events). The importance of capturing youths’ voices provides insight into cyber-behavior as a significant number have experienced cyber-bullying as a cyber-bystander (Spears & Kofoed, 2013). For example, after viewing the Facebook ‘defriending’ scenario, students were asked, ‘Are people at your school ‘defriended’ like this?’ Whilst 470 students replied with *never*, 199 replied *once or twice*, 21 stated *2-3 times a month*, 8 identified about *once a month*, and 5 students declared *several times a week*. Given this prevalence and authentic insight, we begin to explore the power of peer relations on cyber-bystander behavior by understanding the roles of the peer group members in this scenario.

RESULTS AND DISCUSSION

What Roles do Tayla, Sam, Bec, Katie, and the Peer Group Play?

Bullying, whether face-to-face or online, does not occur without an audience. In most bullying situations, there is a bully, victim, and a number of bystanders. Each of these play a role in determining what happens. In the Facebook 'defriending' scenario, Katie is the victim, as she is the target of the bullying, i.e., 'defriending'. Katie's actions were described as being trivial by a number of students who believed that 'defriending' her was a harsh way to act, suggesting that there may be some behaviors that warrant 'defriending'. The bully, in this instance, was Tayla as she instigated the bullying by emailing all the boys and girls that she knew to encourage them to 'defriend' Katie. She is, therefore, considered a 'typical' bully (Björkqvist, Ekamn & Lagerspetz, 1982; Olweus 1978).

Sam, played a dual role, being considered both as a bully and a bystander. As a bully, he is considered a 'henchman' bully as he suggested 'defriending' Katie and supported Tayla's actions (Olweus, 1978, 1991). Henchman bullies rarely instigate bullying but they do join in and become involved. On the other hand, Sam is a bystander, a view supported by 332 students in our research, who identified him as being someone who could have actively stopped the bullying from occurring. Many of these students highlighted that Sam should not have suggested 'defriending' Katie and that he was responsible for what had happened despite not acting. Instead, some believed that he should have discouraged Tayla from acting in a way that would bully Katie and they encouraged him to adopt a more proactive approach by telling Tayla to calm down, such as saying that *'He could have cooled the situation down and realized the consequences'*. Sam also could have actively supported Katie by telling her what was happening; however by doing nothing he was a bystander who enabled the bullying to take place. Some students suggested that he should have encouraged Tayla to send an apology to Katie after the 'defriending'; however this would have done little to stop the bullying at the time. Despite students acknowledging Sam's role in the Facebook 'defriending', very few thought that he would be likely to intervene. Other bystanders who could have intervened included those who received Tayla's request to 'defriend' Katie and others who may have been aware of what was going on, such as friends of friends.

Who Are the Bystanders and How Can They Help?

It is often difficult to identify bystanders, particularly when they are online; therefore accessing the voice of youth who regularly use social media, such as Facebook is important. A number of individuals and groups were identified by students as bystanders in the above scenario.

Friends on Facebook *'didn't have to defriend Katie'* and these friends were identified by the majority of students (n = 583) in the present study as being in the best position to help Katie and stop the bullying. This group of friends hold the power to decide whether to 'defriend' Katie or ignore Tayla's request, therefore influencing the outcome and impact of the bullying. The need to warn Katie about what was going on and support her was raised consistently. Comments, such as *'if everyone was supporting her, Tayla would look stupid'*, highlight the

important, yet complex, role that peers can play in determining who has the power and what the outcome might be. Peers learn social skills and group norms from each other (Rubin, Bukowski & Laursen, 2009). In order to belong and be accepted young people are influenced by what the peer group deems to be appropriate and acceptable behavior. In bullying situations, peers can therefore reinforce the bullying by joining in, supporting the bully, or alternatively they can support the victim or confront the bully about their actions. By telling *'Tayla that her behavior isn't appropriate'*, the peer group is sending a clear message about their group norms. If Tayla desires continued acceptance and belonging within this group, she needs to change her behavior, and thus the *'defriending'* will potentially stop.

Students often take matters into their own hands by either choosing to *'defriend'*, support the victim, or by confronting the bully, as indicated by our findings. Some students, however, choose to deflect their responsibility and instead exercise agency *'by reporting the situation to someone like a teacher or someone of authority'* such as those on Facebook. Mirroring Tayla's behavior, some act by deleting her from their Facebook for being mean.

Bec was identified as a bystander by many students ($n = 370$) in this situation. *'By telling Katie what was happening', 'remaining her friend', and 'not deleting her and standing up for Katie'* were considered important ways of helping. Again, students highlighted that although *'she did help by telling Katie what was going on. She could have taken the next step by having a word to Tayla and telling her that what she was doing was wrong'*. Bec could have also acted further by *'telling everyone not to delete her [Katie]'* as this may have diffused the situation by preventing *'everyone else from 'defriending' her'*. In addition, Bec could have deflected her responsibility to act by *'doing what she did and also reporting it to the people at school' or 'report[ing] it on Facebook'*.

Friends at school were also recognized by students as bystanders in this scenario. This group of friends plays a role in both the online and offline settings, and are known as hybrid bystanders (Price et al., 2014). Regardless of the setting, the onus to act and support Katie was emphasized by students who suggested that friends should *'accept her for who she is and support her the next day'* and *'help Katie when they see her in school'*. These comments highlight the online/offline flow that often occurs in cyber-bullying situations where relationships between the face-to-face and cyber contexts shift and change rapidly (Cross et al., 2009; Price et al., 2014; Spears, in press; Spears, Slee, Owens, & Johnson, 2009). This group of friends were seen as the bystanders who out of all those identified should report the incident to a teacher or another authority figure. Friends at school were deemed to be in a unique position due to their awareness of what occurs in both contexts and they have the power to report it in both the online and offline environments, suggesting that these hybrid bystanders may play a very influential role. Online, these bystanders could also have ignored the message that Tayla sent, while offline they could support Katie either by remaining her friend or telling her what was happening. It was also suggested that these friends should confront Tayla about her request to defriend Katie suggesting that they should *'confront Tayla for being: (a) mean to her classmates, and (b) for her psychologically challenged thinking that 'defriending' people on Facebook would make them have no friends in real life'*. This comment suggests that *'defriending'* someone online has no effect on the offline environment; yet paradoxically bystander behavior appears to have no boundaries as students report that friends at school should support and remain friends with Katie.

Surprisingly, others online were identified by only a few students as bystanders ($n = 139$) and therefore this group was seen as the least likely to intervene. It was suggested that this

cohort should ignore Tayla's request to 'defriend' Katie and/or report the incident to an authority figure.

What Makes a Cyber-Bystander Help?

Bec, as Katie's friend, was considered to be the most likely person to help ($n = 384$). *'Because they are friends'* was continually used to explain why she should help, implying a universal understanding of what is expected of a friend. Friends on Facebook and friends at school were also considered likely to intervene to help Katie. Their role as friends on Facebook (including Bec) was complex as they are recognized as bystanders online and expected to support Katie not only online but also offline at school, supporting the idea that they are hybrid bystanders (Price et al., 2014).

So, why would someone help Katie? Students identified a number of reasons why cyber-bystanders may intervene. Being friends either on Facebook or offline was identified as the main reason that influenced bystander behavior. This highlights both the significance of peer relationships and the complexity that lies within being part of a peer group. Comments, such as *'they are friends on Facebook for a reason, they're her friends'* and *'therefore they would be looking out for her and supporting her'* suggests that certain rules apply among friends. For these students, if *'they are friends ... they have to respect their friend,'* which means *'they would not tolerate Tayla's bullying'* and would *'support her and help her'*. Peer relationships are complex. Young people are often torn between following Tayla's request, maintaining a sense of belonging among peers, or following the social conventions of friendship and supporting Katie.

Doing the right thing and acting morally was also described as a key influence in bystander behavior, suggesting that cyber-bystanders may act because *'they know that it's wrong to do to someone'*. This comment highlights the moral thinking that may underpin cyber-bystanders' thinking. Having empathy for Katie also influenced cyber-bystanders' decision to intervene or not in this Facebook scenario. Descriptions such as *'she knew how it would feel and she didn't want to do that to Katie'* and *'she put herself in Katie's shoes'* consistently supported students' views that feeling sorry for Katie and seeing the scenario from her perspective, helped bystanders intervene. These students made suggestions about how bystanders in this hypothetical scenario might act; however this may not portray how they would act themselves if faced with a similar situation.

How Would You Act in a Similar Situation?

What would you do if you were asked to 'defriend' someone on Facebook? Agency in reporting the incident to a teacher or someone in authority featured consistently in students' responses. While *'teachers have the power in the school'*, *'the Facebook administrator might ban the person who sent the email to make her think she wasn't so clever after all'* therefore, *'by reporting it online you can get higher levels of authority involved hopefully getting the bully in serious trouble and hopefully they won't bully anyone else ever again'*. Students also argued that *'teachers can't control what happens on fb [Facebook] and out of school hours'* and *'it's nothing you can sort out with the teacher it's the people's choice so leave it to them because a*

lot of the time a teacher makes it worse'. Despite good intentions, there were some students who chose not to act because they feared the consequences from their peers and thus these students explained *'by reporting to a teacher, I would stay anonymous to my peers and help resolve the problem'*. This enabled the student to do the right thing without retribution. Others simply would not get involved because *'we'd be targeted if we were on her side'* and they *'wouldn't want to become another target'*.

Gaining or maintaining a sense of belonging and being accepted is a powerful influence on people's actions. For example, students described wanting *'to help my friend but I wouldn't want everyone to hate me'*. In this instance, students may join others in 'defriending' Katie or they may fail to intervene so that they maintain their sense of belonging among their peers. For many, social media is paramount in their lives as it provides a platform to interact with peers and gain a sense of belonging. Yet, for others *'having no friends on Facebook doesn't mean anything at all'* because it is not about *'who are friends with you on fb [Facebook] it's about real life that counts'*. Ensuring that the victim feels a sense of belonging and acceptance can motivate bystanders to act *'so they don't feel they don't have friends and make them feel better'*. Friendship again featured consistently in students' responses, highlighting the complexity and importance of these relationships. Students will act *'because she is my friend'* which demonstrates their understanding of the rules of friendship. Relationships, sense of belonging and acceptance are important to young people and these elements of their life underpin and motivate their actions.

It is argued that one difference between bullies and bystanders is their ability to feel empathy for others (Olweus, 1991; 1994). Understanding what it must be like to be 'defriended' motivates bystanders to intervene *'because they would be heartbroken when they don't have any friends on Facebook'*. Some students feel guilty about what is happening to Katie and therefore they *'help her because I would feel awful that the girls or other students are targeting her and making her feel like a loser'*. The need to *'stand up for what is right because you wouldn't want it happening to you'* was also consistently echoed by students as reasons for intervening in this situation.

What Might Make Cyber-Bystanders Decide to 'Defriend' Katie and Support Tayla?

Despite some young people's empathy for victims, the fun, entertainment, and enjoyment of seeing peer reactions to adverse situations may adversely influence cyber-behavior. For some young people, 'defriending' Katie was *'hilarious'*, whilst others seemingly diffused the seriousness of such action by brushing it off as a *'light hearted joke'*. If peers think the act of 'defriending' is funny, then joining in on such behavior seemingly promotes peer acceptance (Green, 2014). Such *'mob mentality'* described by one participant, identifies how some individuals do not want to *'be accused of ruining'* the fun or being labelled *'stupid'* or *'a loser'*. If everyone else is doing it, then it must be okay. What was noticeable and in contrast to findings by Olweus (1991; 1994), was the lack of empathy in peer responses for how Katie might feel about being 'defriended' or the potential hurt and emotional consequences that it may cause. Whilst a few peers were empathetic, a significant proportion were extremely egocentric in their behavioral decision making in relation to how it might impact on their own social status, particularly their image and recognition from the *'cool'* or *'popular'* people. Young people

described Tayla as the *'coolest in the school'*. Her reputation and status may have influenced cyber-bystander behavior as adolescents, who are highly susceptible to peer influence, and wished to attain social desirability and the status of being *'cool'*. Subsequently, they support the bully's behavior as they are *'not wanting to be seen helping the loser'*.

The importance of belonging to a peer group identified as the *'beautiful people'* (Price et al, 2014), was driven by adolescent desire *'to be part of the crowd'* and not wanting to *'be seen as different'*. Such rationale was reflected in comments stating that they *'wanted to look like everyone else and fit in even if it meant bullying of some sort'*, like *'defriending'* Katie. The peer pressure of conforming to group norms was identified as a key influence on cyber-behavior and may be present as a major reason why cyber-bystanders might support popular people like Tayla and *'defriend'* Katie. Lack of conformity *'risks losing popularity'*, and *'being left out'* with *'fear of losing Tayla as a friend or being shunned by friends'*. Supporting the victim was deemed as *'social suicide'* and *'weak'*, whereas *'defriending'* Katie *'may help somehow in social hierarchy'*. Fear of exclusion seemingly clouded cyber-bystanders' behavioral judgements as *'in society it's all about being in a group and people want to be accepted'*. This raises the issue of the social-ecological factors which influence such societal attitudes and how these can be shifted so that positive cyber-bystander behavior is enacted.

In aspiring to be recognized as part of the cool group, individuals may feel pressured or intimidated to act regardless of whether they perceive the act to be inappropriate, harmful, or against the law. Feeling *'scared'* of the power exercised by someone they aspire to connect with and the ability to be recognized may override moral reasoning whereby they undertake acts, such as *'defriending'* on Facebook.

This notion of power and intimidation creates feelings of being *'afraid'* and not wanting to end up being at the receiving end of the person with power where they become the *'victim'*. They need to be seen to be on the good side of the *'cool'* person, not the *'bad side'* so they are not the brunt of retaliation, physical or mental abuse, or being *'defriended'* on Facebook. *'If you mess with a popular girl she will get all her friends onto you and make your life hell'*. This notion of being *'destroyed'* by such powerful people was an underlying rationale for decisions and behaviors. It created necessity to take sides between Katie and Tayla, with many choosing a safe option of the popular and powerful girl as the retaliation would impact on friendships, inclusion, and becoming a victim of bullying. This feeling of being controlled due to intimidation and being scared was common reasoning for young people in their reasoning for cyber-bystander behavior. And for some, in relation to being *'defriended'*, they were *'just glad it wasn't me'*.

Further reasons for *'defriending'* Katie revolved around *'dislike'* of the victim or lack of *'care'* and in a few cases they *'want to see the victim get hurt'*. This lack of empathy and moral engagement by cyber-bystanders is addressed by Price et al. (2014). For some cyber-bystanders, as in the Facebook *'defriending'* scenario, they *'don't see the potential harm'*, reasoning *'it wasn't that bad'* as their own focus was primarily on social acceptance within the cool group. For others, they argue that there were *'good reasons'* for such actions which promoted *'fairness'* for settling the issues in such a manner. This implies an element of justice being served and that the victim, Katie, deserved being *'defriended'*. *'Because she's been a bitch to all of them and they want to get her back'*. Therefore, *'defriending'* Katie was *'an apt punishment'*. For many adolescents *'defriending'* was just the *'right'* action to take. So in light of these suggested reasons for why cyber-bystanders may choose to become involved in either

positive or negative cyber-bystander behavior, what are the social-ecological influences at play?

SOCIAL-ECOLOGICAL INFLUENCES ON CYBER-BYSTANDER BEHAVIOR

The digital revolution has connected people across the globe twenty four hours a day, encouraging a range of interactions, collaborations, and relationships previously unimagined or experienced. ‘The mobile/cell phone has transformed peer groups into a truly networking group’ (Campbell, Butler & Kift, 2008, p. 1). Young people’s continual access to social networking sites creates ongoing decision making about their cyber-behavior and while many display responsible actions, cyber-bullying continues to be a major societal concern. If peer groups are now truly networked and interconnected every second of the day, then in the context of this scenario, to be ‘defriended’ in one setting can and will affect their social worlds. Therefore, for cyber-bystanders to play a productive and pro-active role in social networking forums, such as Facebook, what are the social-ecological factors that influence their behavior?

Within this chapter we have examined the heart of the friendship/peer group microsystem interactions that traverse between the online social networking forum, such as Facebook, and the school microsystem. The influences of peer acceptance, belonging, group norms, hierarchical power, and friendships were suggested to strongly determine the effectiveness of relationships within the microsystem and a cyber-bystander’s subsequent behavior. However the power of peer relations in cyber-bystander behavior was seemingly influenced by a wider range of social-ecological factors which filter into the online social media platform and which we suggest are equally important in advancing initiatives to prevent cyber-bullying.

Home/family life has a significant influence on the attitudes and values that adolescents form. However, the ‘digital divide’ between a young person and their parents may create competing beliefs and knowledge regarding online platforms and the associated behaviors when using them (Pearce, Cross, Monks, Water & Falconer, 2011). Cyber-bystander initiatives of defending victims by reporting incidents such as those highlighted in the ‘defriending’ scenario may be undermined by parents/caregivers who threaten restrictions to young people’s use of technology (Keith & Martin, 2005). When confronted with a range of differing attitudes and values across parent/caregivers, peers and the educational school values and individual classroom teacher’s perspectives, a powerful concoction of conflicting, conforming, and aligning values may emerge. These complex mesosystem interrelations (Bronfenbrenner, 1979) across home, school, and online platforms, may challenge the adolescent in forming their own beliefs and attitudes or upholding them across a range of settings. For example, engaging on a social media platform, the limited presence of authority figures including parents and teachers, may sway cyber-behavior toward peer group norms and socially desirable attitudes.

Further to this, at the exosystem level (Bronfenbrenner, 1979) decisions regarding the social media platform design, accessibility, policies and authorization may influence a young person’s actions online. For example, increased access and insecure privacy settings may result in inappropriate use and unsafe online behavior. At the chronosystem level (Bronfenbrenner, 1979), the impact of time critical factors also influence behavior. Increased internet speed may provide faster capacity to send messages and gain instant replies whereby decision making may

be impulsive when ‘defriending’ someone like Katie, lacking the time needed to think about the consequences.

At the macrosystem level (Bronfenbrenner, 1979), policy and legislative decisions aim to influence cyber-bullying and cyber-bystander behavior. In Australia, bullying and cyber-bullying are not considered criminal offences, yet their place in civil law continues to cause debate (Campbell, Butler, & Kift, 2008). As technology diversifies and we learn more about cyber-crimes, this may change. Given these ‘grey areas’ with no distinctive legislation, people continue to bully or act as a bystander who follows, reinforces, or just watches cyber-bullying take place without getting uninvolved, as there is no requirement to do so. Under civil law, schools have a duty of care. Lord Esher, citing the legal case of *Williams and Eady*, described the duty of care of a teacher as being at the same level as ‘a careful father [who] would take care of his boys’ (as cited in Campbell, Butler & Kift, 2008 p. 8). There is also an onus on the victim to report cyber-bullying to authorities as they need to be seen to have taken practical precautions. Victims can sue bullies and school authorities. The most likely outcome is negligence on the school’s part in preventing cyber-bullying (Campbell, Butler & Kift, 2008). Australian schools are required to have anti-bullying policies; however, whether these address cyber-bullying is contentious. Given the rapid technological advancement, many schools are grappling to keep abreast in updating their policies to adequately address cyber-bullying. In addition, given cyberspace has no geographical boundary, it makes it difficult to determine who has jurisdiction (Campbell, Butler, & Kift, 2008). This is compounded by the hybrid bystanders who traverses the online and offline environments, viewing this as only one environment (Price et al., 2014). These mixed and undefined policies underpinning cyber-bullying filter into the online social media platforms creating diverging online behavior. Adolescents who are risk takers may challenge authority by engaging in risky bystander behavior, whilst others may conform. As emphasized through this chapter it could be summarized that the power of peer relations may override some cyber policies.

The school microsystem has been extremely proactive in attempting to educate school communities about positive uses of technology and online behavior. A range of stand-alone school based programs have been implemented; however, these programs are not as effective as whole-school approaches in addressing bullying (Cross et al., 2011; Smith, Schneider, Smith, & Ananiadou, 2004; Vreeman & Carroll, 2007). Whole-school approaches are underpinned by an ecological systems approach where bullying is targeted at multiple levels. For example, at the school level, policies aimed at fostering a positive classroom and school ethos, addressing behavior, implementing peer support, and school yard improvements are employed. In addition, initiatives are integrated at the classroom level, home level by engaging and involving parents and caregivers, and an individual level by working with students who are at risk of being victimized or engaging in bullying behavior (Cross et al., 2011). This whole school approach aims to empower all stakeholders while providing an environment where bystanders feel that they can intervene. Such initiatives are supported by the National Safe School Framework’s (Education Services Australia Ministerial Council on Education, Early Childhood Development and Youth Affairs, 2011) whole school approach which ‘provides a vision and a set of guiding principles for safe and supportive school communities that also promote student wellbeing and develop respectful relationships’ (p.2). In essence, applying ‘an ecological perspective can influence everyone’s sense of wellbeing and belonging to a community’ (McCallum & Price, 2016).

CONCLUSION

The power of peers in determining cyber-bystander behavior played a significant role in the eyes of youth. Employing resilience in being confident with ‘well developed positive peer relationships, bouncing back from adverse situations and events’ (Nolan, Stagnitti, Tacket & Casey, 2014, p. 241) was also inclusive of broader social-ecological factors including the role of families and significant others, policies and programs. In responding to the ‘defriending’ scenario, young people (12-18 years) indicated that they would use a number of strategies if they were bullied online. The most common of these was to avoid the person, block them, or report what was happening to an online authority. Secondly, this group indicated that they would look for support from parents. To prevent further escalation, some of these young people said that they would confront the perpetrator (Vandoninck & d’Haenen, 2014). However, for many young people responding to this scenario, their reasoning and decision making of cyber-bystander behavior was influenced by their egocentric desire to belong or be recognized by the dominant ‘popular’ people.

The challenge in addressing cyber-bullying is how to direct adolescent preoccupation of being influenced by their peers (Rubin, Bukowski, & Larsen, 2009) into proactive behaviors which are agential in overcoming hierarchical power, group norms, and social status. Whole-school approaches and broader community initiatives need to promote an increasing understanding of cyber-bullying and advocate positive cyber-bystander behavior as ‘cool’. This is where everyone as a cyber-bystander does more than ignore or report incidences, rather elicits peer power to enact positive online relationships and interactions. For these youth, victims need more than just friends to stand up and counteract cyber-bullying, as everyone plays a role whether within the online social media microsystem or across the broader ecological meso, exo, macro and chronosystem. Remember, social behavior is never a function of the individual, it is influenced by the company they are in and the broader social-ecological influences.

So when reflecting on this chapter, you may wish to consider the following:

- How do you individually behave as a bystander?
- What influences your behavior and attitudes?
- What role can you play in empowering positive and proactive bystander behavior?

INTRODUCTION

This chapter is intended to provide an understanding of cyberbullying among young people from teachers' perspective. Academic research into this topic is relatively recent; however, due to the increased usage of computers and mobile phones by young people, cyberbullying has attracted a lot of interest and media attention (Ybarra & Mitchell 2004; Patchin & Hinduja 2006; Li 2007; Kowalski et al., 2008; Shariff 2008; Smith, Mahdavi, Carvalho, Fisher, Russell & Tippett 2008; Sourander et al., 2010). Whilst using mobile phones and computers for communication purposes has many advantages, it can also bring some negative experiences, such as unwanted aggressive messages (e.g., Smith et al. 2008; Vandebosch & Van Cleemput 2008), flaming (e.g., Smith et al., 2008), happy slapping (e.g., Smith et al., 2008), and sexting (e.g., Spears, Slee, Owens & Johnson 2009).

The purpose of this chapter is to discuss the vital role teachers play in the prevention and management of cyberbullying. Throughout the chapter, the importance of understanding teachers' perceptions of cyberbullying is emphasized as the necessary first step to help them develop a good recognition of bullying and develop the skills needed to deal with it. Consideration is first given to cyberbullying in the global research context (i.e., the conceptualization, the prevalence, the outcomes) to help the reader appreciate the importance of this work on a wider scale, not only in the United Kingdom, where the research project is based. Following this, research undertaken by the authors is presented. Based on in-depth

* Corresponding Author's Email: m.marczak@bbk.ac.uk.

interviews with 28 teachers (18 females (64%) and 10 males (36%)) from 5 different schools from the West Midlands region in England, the research was able to capture teachers' perceptions of cyberbullying, their understanding of its impact on young people's health and lives, their readiness to act when incidents of cyberbullying take place, and finally the support the teachers voiced they need to help them prevent and manage cyberbullying within educational settings (Marczak 2014). In conclusion the chapter highlights the value of Bronfenbrenner's ecological framework (1979) when evaluating current and future interventions aimed at cyberbullying prevention and management.

WHAT IS CYBERBULLYING?

Cyberbullying refers to bullying and harassment of others using new electronic technologies, the most popular being the internet and mobile phones (Ybarra & Mitchell 2004; Patchin & Hinduja 2006; Kowalski et al., 2008; Shariff 2008; Smith et al. 2008; Sourander et al., 2010). New technologies, such as personal computers and mobile phones, have become omnipresent in our society (Kowalski et al., 2014). Research conducted by the EU Kids Online network in 2011 indicated that 60% of 9-16 year old internet users in Europe go online daily, and a further 33% go online at least weekly, with 49% using the Internet in the privacy of their bedrooms. The Internet is used by adolescents on a daily basis and research shows that the majority of 'online youths' are using it to send e-mail or instant messages (Livingstone, Ólafsson & Staksrud 2011). Other popular uses reported among those surveyed include school-related research, obtaining news information, getting information about movies, music, and television, and looking up health information (Kanuga & Ronsenfeld 2004). With somewhere between 75% and 83% of adolescents having Internet access at home, and nearly all having access at school, the vast majority of them are able to go online whenever they like.

These numbers paint a picture of how new technologies are used by youths, both in and out of schools, and although appropriate use of the Internet can enhance student learning, these new technologies also increase the likelihood of using them for negative purposes, such as cyberbullying (Patchin & Hinduja 2006). The anonymity, the lack of supervision in chat rooms, and the possibility of being able to contact others anytime, anyplace, are all purported to contribute to increased opportunities for cyberbullying. Although the majority of cyberbullying incidents take place outside educational settings, they involve school and usually classroom-based relationships (Slonje & Smith 2008). It has been reported that despite the rates of traditional bullying decreasing in many countries, the rates for cyberbullying incidents seem to either be stable or increasing. This may be due to the fact that technology continues to develop (e.g., the appearance of smart phones) and that social networking sites have been increasing in popularity among young people (Rigby & Smith 2011).

A review of literature suggests that although this area of research has recently become very popular there is still considerable amount of unanswered questions (Slonje & Smith 2008). To date the extent research has focused on providing information on the phenomenon, clarifying issues of measurement, and exploring its impact and implications (Smith & Sittichai 2009). Tokunaga (2010) highlighted the need for research to further define and conceptualize cyberbullying to reduce methodological problems in future studies.

CONCEPTUAL DEFINITIONS

Similar to traditional bullying, there is no universal definition of cyberbullying available. The earliest studies adopted existing definitions of school bullying proposed by Olweus (1993) and adapted these definitions to the online environment. Some of these definitions have been accepted by the researchers investigating cyberbullying and they are currently being used in studies conducted across the world (Marczak & Coyne 2015).

As previously discussed, few problems exist when defining traditional bullying and these have to be considered when defining cyberbullying. The definition of traditional bullying includes intended or purposeful harmful behaviors or acts which need to be repetitive in nature and includes a victim who is 'weaker' either physically or mentally than his/her perpetrator(s). As cyberbullying is a type of bullying, all of those aspects should apply to it as well. Although all of the cyberbullying definitions used in studies accentuate the essential aspects of cyberbullying (i.e., the intention to harm, repetition, and power imbalance between victim and perpetrator) and these components are widely accepted (Dooley, Pyzalski & Cross 2009), they still rise some controversy among researchers (Necentini, Calmaestra, Schultze-Krumbholz, Scheithauer, Ortega & Menesini 2010).

Intention

Some researchers have argued that because of the indirect nature of cyberbullying it is very difficult to establish the intention of this behavior (Menesini & Nocentini 2009; Slonje & Smith 2008). This stance was followed by other researchers challenging the importance of the intention to cause harm aspect within the definition of cyberbullying (Langos 2012; Nocentini et al., 2010). They argued that at times even when messages were sent as a joke and not meant to harm, they affected the victim in the same manner. Therefore, it was suggested that the criterion used should be the victim's perception of the perpetrator's intention and the impact the message(s) had on the victim (Grigg 2010).

Repetition

Langos (2012) argued that a single act of aggression is not sufficient to be classed as a direct form of cyberbullying, and that the negative behavior has to happen on more than one occasion, making this criterion similar to traditional bullying. However, in circumstances where a perpetrator posts an electronic communication in a public forum, a public blog, or creates a 'hate page' (i.e., in the act of indirect cyberbullying), it is no longer necessary for the victim to prove a course of behavior to satisfy the criterion of repetition. In such circumstances even one single act can have infinite scope in terms of the velocity with which it propagates and/or is being accessed by a large volume of people. Moreover the message, page, or blog can be saved and then accessed at a later point in time and/or re-posted. This means that others can repeat the original perpetrator's single act of behavior and that the victim may experience it repeatedly (Menesini & Nocentini 2009). Hence, as the victim can be harmed repeatedly by one single act

of cyberbullying, the traditional repetition criterion does not automatically have to be met (Marczak 2014).

Power Imbalance

Power imbalance is pervasive within definitions of traditional bullying, as physical bullying often involves a larger individual exerting his/her physical power over a smaller or weaker individual (Atlas & Pepler 1998). However, in an online environment, the perpetrator's physical size does not make any difference, as even the smallest and physically weakest individual can engage in cyberbullying. Instead, it is the nature of the power that is different, as those who are more technologically savvy seem to hold the power (Law, Shapka, Hymel, Olson & Waterhouse 2012). Cyberbullies think of themselves as better Internet experts in comparison with those who do not cyberbully others and students who had more advanced Internet skills were more likely to experience deviant Internet and mobile phone activities (Vandebosch & Van Cleemput 2008; Ybarra & Mitchell 2004). This technological power is also characteristic of virtual worlds, such as Second Life. Chesney, Coyne, Rivers, and Madden (2009) concluded that a virtual world is a specific environment in which those with a greater expertise may become more powerful than others and therefore these individuals have more opportunity to intentionally harm others.

Examining this issue from the victim's perspective, Dooley, Pyzalski and Cross (2009) argued that power in an online environment is based on the victim's lack of power and not necessarily on the perpetrator's possession of power. They believed that as the material exists in cyberspace, the environment itself makes it more difficult to remove or to avoid it as it can be circulated, saved, reposted, or edited and amended by people other than the original perpetrator, which in turn can make the victim feel more powerless (Dooley, Pyzalski & Cross 2009).

Defining cyberbullying may not be as clear cut as defining traditional bullying. The debate on how and whether to adopt the criteria of intention to harm, repetition, and power imbalance associated with traditional bullying definitions continues (Marczak 2014).

DIFFERENT FORMS OF CYBERBULLYING

Smith et al. (2008) identified seven types of cyberbullying, depending on the type of technology used:

- Text message bullying
- Picture/video clip bullying (including taking a picture or a clip of someone using a mobile phone camera and then sending it to others or uploading it on a website as well as happy slapping – a physical attack on a person which is filmed by others but with the full knowledge of the perpetrator)
- Phone call bullying (includes silent or abusive calls)
- Email bullying (includes sending or receiving abusive emails)
- Chat-room bullying (being abusive or being abused whilst using chat rooms)

- Instant messaging bullying
- Bullying via websites (includes creating a hate page which contains abusive information direct to a specific person or uploading abusive information on an already existing hate page).

Cyberbullying can also take different forms of behavior, and although several studies investigated its different forms, Willard (2006) proposed a categorization, which included a formal definition for each form of behavior:

- Flaming – “sending angry, rude, vulgar messages” (p.1) to a person or to an online group
- Harassment – “repeatedly sending offensive messages” (p.1) to a person
- Cyberstalking – “repeatedly sending threats of harm or highly intimidating messages” (p.1)
- Denigration (put-downs) – “posting untrue or cruel statements” (p.1) about a person to other people
- Impersonation – “pretending to be someone else to make that person look bad or place in danger” (p.1)
- Outing and Trickery – includes “posting material that contains sensitive, private information about another person” and engaging “in tricks to solicit embarrassing information that is then made public” (p.1)
- Exclusion – “intentionally excluding a person from an online group” (p.1).

Rivers and Noret (2010) listed ten categories of behavior. These included threats of physical violence, abusive or hate-related and/or homophobic name calling, death threats, threats to family/home, menacing chain messages, threats to damage existing relationships, ending of platonic relationship, sexual acts, and demands/instructions. Slonje, Smith and Frisen (2013) also acknowledged other modes of cyberbullying, such as sexting (which includes distributing sexualized images using mobile phones or the Internet without a person’s consent), trolling (i.e., uploading or posting persistent abusive comments on a website), and grieving (i.e., harassing someone in an online game or virtual world). In summary, a variety of cyberbullying has been studied through delineating types of behavior and the media used.

Langos (2012) has also made a distinction between what constitutes direct and indirect cyberbullying. As such, direct cyberbullying takes place in the private domain and involves electronic communications from the perpetrator and targets solely the victim. It may encompass a perpetrator making direct phone calls to a victim’s mobile phone, sending e-mails to a victim’s personal e-mail account, or sending SMS messages to a victim’s mobile phone. Indirect cyberbullying occurs in the public online space and it includes material that has been uploaded onto a webpage and is easily available, such as posting in a public forum or a public blog.

PREVALENCE RATES

Previous research investigating the prevalence rates of cyberbullying among adolescents has primarily focused on two categories of involvement, i.e., cyber-victims and cyberbullies

(Marczak & Coyne 2015). The prevalence rates of cyberbullying found in these studies ranged from 10% to 72% (Hinduja & Patchin 2008; Hoff & Mitchell 2008; Juvonen & Gross 2008; Mishna, Cook, Gadalla, Daciuk & Solomon 2010). Research carried out for the Anti-Bullying Alliance (ABA) found that 22% of 11-16 year olds in their sample had been a victim of cyberbullying (Smith & Shu 2000; Smith, Mandavi, Carvalho & Tippet 2005). The MSN cyberbullying report (2006) found that 11% of UK teens had experienced cyberbullying. River and Noret's (2010) four-year study investigating cyberbullying found that 15% of the 11,227 participating children had received nasty or aggressive text messages and emails, and that there was a year-by-year increase in the number of children who were being cyberbullied. Results from studies conducted as part of the Department for Children Schools and Families' (DCSF; 2007a) cyberbullying information campaign found that 34% of 12-15 year olds reported that they were cyber victims.

Kowalski et al. (2014) suggested that the discrepancy in reported rates of cyberbullying may depend on the most popular method of online communication used by the sample at the time of the research being conducted. The various methodologies used within the studies conducted to date make it difficult to compare rates of cyberbullying across countries and over time. Moreover, some studies used a very specific time frame (e.g., within the last year) when asking students about when a cyberbullying incident took place, which could have led to the results showing reduced cyberbullying prevalence rates (Ybarra 2004; Williams & Guerra 2007; Wolak, Mitchell & Finkelhor 2007; DeHue, Bolman & Vollink 2008; Ybarra & Mitchell 2008). Other researchers did not use a time frame and reported higher rates of cyber-victimization (Raskauskas & Stoltz 2007; Hoff & Mitchell 2008; Juvonen & Gross 2008; Mishna et al., 2010).

Moreover, Slonje, Smith and Frisen (2013) acknowledged that in many of the studies on prevalence rates reported a different number of media used among the participants. For example, Smith et al. (2008) included seven (i.e., mobile phone calls, text messages, picture/video clip bullying, e-mails, chatroom, instant messaging, and websites), Hinduja and Patchin (2010) used nine, and Wachs and Wolf (2011) investigated five types of technology. Furthermore, it is important to note that with the emergence of smart phones, different online communication media can be accessed using a single mobile phone (Marczak & Coyne 2015).

Although the majority of the studies published to date were conducted in one country some attempts have been made to compare the cyberbullying phenomena across different countries within a specific timeframe. These included three international projects such as the European Daphne Programme (with three countries cooperation: Italy, Spain and England), EU Kids online (thirty three countries), and COST Action ISO801 (thirty countries in total) (Marczak & Coyne 2015).

The majority of the studies conducted to date employed quantitative methodology, exploring the phenomenon of cyberbullying through online or face-to face questionnaires (Li, Smith & Cross 2012). Whilst they use different self-assessments (i.e., global item assessment versus specific item assessment), these approaches have their own limitations, which may explain the differences in reporting prevalence rates of cyberbullying (Gradinger, Strohmeier & Spiel 2010; Marczak 2014).

AGE AND GENDER DIFFERENCES

Although cyberbullying occurs among people of all ages in varying degree, most research examining this phenomenon has been conducted on children and adolescents (Tokunaga 2010). Findings have differed with regards to age, with some studies indicating a significant relationship between age and cyber-victimization (e.g., DeHue et al., 2008; Hinduja & Patchin 2008; Kowalski & Limber 2007; Slonje & Smith 2008; Ybarra, Diener-West & Leaf 2007; Ybarra & Mitchell 2008) and others reporting no association (e.g., Beran & Li 2007; Didden et al., 2009; Juvonen & Gross 2008; Katzer, Fetchenhauer & Belschak 2009; Patchin & Hinduja 2006; Smith et al. 2008; Varjas, Henrich & Meyers 2009; Wolak et al., 2007; Ybarra 2004).

Although it appears that gender is an important factor influencing cyberbullying, inconsistent findings have also been reported regarding gender differences (Hinduja & Patchin 2010; Keith & Martin 2005; Smith et al. 2008; Tokunaga 2010). Keith and Martin (2005) proposed that since cyberbullying is similar to relational forms of traditional bullying, and because girls engaged in more relational bullying, then girls would be more likely to be cyberbullies. However, while some studies (e.g., Rivers & Noret 2010) have shown that girls were more involved than boys, some (e.g., Calvete, Orue, Estevez, Villardonm & Padilla 2010; Fanti, Demetrium & Hawa 2012) have indicated that boys were more involved than girls, and others (e.g., e.g., Livingstone, Haddon, Gorzig & Olafsson 2010; Smith et al., 2008) report no significant gender differences. The inconsistencies regarding age and gender differences may be due to different samples or methodologies used across the studies (Slonje et al., 2013).

RISK FACTORS

A considerable amount of studies have tried to identify risk factors associated with cyberbullying, with the emphasis being placed on demographic and behavioral factors. Sparse research has investigated the predictors of cyberbullying and their similarities and differences to those associated with traditional bullying (Marczak & Coyne 2015). Research however has shown that intensive use of the Internet emerged as a risk factor for cyber-victimization (Wolak et al., 2007). Initial investigations from the USA (e.g., Ybarra & Mitchell 2004; Patchin & Hinduja 2006; Willard 2006) and Canada (e.g., Li 2006) have shown that children and adolescents who enter chatrooms are subject to psychological stress and aggressive behaviors from other chatroom guests. Other predictive factors of cyber-victimization include location of the computer at home and a lack of awareness of the risks involved in going online (Hinduja & Patchin 2009; Sengupta & Chaudhuri 2011). Furthermore, Ybarra and Mitchell (2004) showed that students who were victims of school bullying were more likely to be cyberbullies. However, Raskauskas and Stoltz's (2007) study did not support these results as they found that victims of traditional bullying were not more likely to cyberbully others, but rather to also be cyber-victims. Their results also showed that those students who were traditional bullies were more likely to have been bullied and to perpetrate cyberbullying.

OUTCOMES OF CYBERBULLYING

Cyberbullying causes harm which appears to be comparable to that caused by traditional bullying (Gradinger, Strohmeier & Spiel 2009; Smith & Slonje 2010). Thus, cyberbullying presents a legitimate cause for concern by schools, teachers, and parents. In comparison to traditional bullying, the impact of cyberbullying experiences has been evaluated in fewer studies. Some have assessed the impact of cyberbullying by comparing its effects with those of traditional bullying. In the most frequent approach used, students were asked about what forms of aggression (face-to-face or online) seem more damaging. Findings suggested that the impact depends on the form of cyberbullying (Smith et al., 2008). Some types of cyberbullying (such as insults and threats) are perceived as less harmful than traditional bullying, whilst others, especially ones using images or videos and with an element of blackmail, are considered more damaging. Ortega et al. (2012) suggested that as the perceptions differ between countries, the impact of cyberbullying may be dependent on the cultural importance given to social relationships that started in cyberspace.

The second approach focuses on the correlates of cyber-victimization. These studies found that the negative outcomes of cyber-victimization, such as lower achievement scores adjustment problems (e.g., depression, social anxiety), and low levels of self-esteem, are similar to those found for traditional bullying victimization (Ortega et al., 2009; Ortega et al., 2012; Tokunaga 2010).

Recent literature on children and adolescent samples showed that cyber-victimization can lead to serious physical, social, and psychological problems (e.g., Finkelhor, Mitchell & Wolak 2000; British Broadcasting Corporation 2006). These studies encompass psychological problems (e.g., Didden et al., 2009; Katzer et al., 2009) and emotional difficulties (e.g., Raskauskas & Stolz 2007; Katzer & Fetchenhauer 2007). Other research showed that cyber-victims are at a higher risk for internalizing adjustment problems (e.g., Gradinger et al., 2009), developing mental health problems (e.g., Brighi et al., 2012), misusing illicit substances (e.g., Carbone-Lopez, Esbensen & Brick 2010), and developing eating disorders (e.g., DeHue, Bolman & Vollink 2008). The direst outcome of cyberbullying is suicide (Hinduja & Patchin 2010).

Furthermore, cyberbullying was linked with a decline in academic performance (e.g., Katzer et al., 2009; Rothon, Head, Klineberg & Stansfeld 2011), not being able to concentrate (e.g., Beran & Li 2005; Juvonen & Gross 2008), decline in school attendance (e.g., Wolak, Mitchell & Finkelhor 2006; Ybarra et al., 2007), lower school commitment (e.g., Ybarra & Mitchell 2004), and a negative school climate (e.g., Williams & Guerra 2007).

BACKGROUND FOR CURRENT STUDY

Research on bullying indicated that the school community plays an important role in bullying-related issues, as teachers, often the first adults dealing with student behaviors, play a significant role in addressing bullying. Teachers' awareness of this issue together with commitment to involve themselves in bullying prevention and management can reduce bullying by 50% (Boulton 1999; Olweus 1991). Given that teachers' behavior is affected by their

perceptions and beliefs, understanding their perceptions is a necessary first step to help them develop a good recognition of bullying and the skills needed to deal with it (Siu 2004).

The close connection between traditional bullying and cyberbullying suggests that teachers' beliefs and behavior may significantly contribute to combatting cyberbullying (Li 2008). Although many educational professionals recognize the problem of traditional bullying, only a small number of educators realize that students may be subject to electronic aggression (Smith et al., 2008; Steffgen, König, Pfetsch & Melzer 2011). Thus, more research is needed to investigate cyberbullying from the teachers' perspective.

ECOLOGICAL MODEL

Using Bronfenbrenner's (1979) ecological system, the World Health Organisation (1999; 2002) has adopted an ecological model to understand the multiple causes of aggressive behavior in terms of the constant exchange of risk factors thought to contribute to such behavior and which operate at four different levels (i.e., individual, relationship, family and societal). Sutton and Smith (1999) proposed a parallel method for understanding school bullying. The main aim of Marczak's (2014) research was to construct an approach that would allow for a better understanding of cyberbullying. The four levels of the ecological model as related to school bullying are presented in Figure 1.

Figure 1. Ecological model for understanding school bullying (adapted from World Health Organisation 2002).

The first level of the ecological model focuses on the personal characteristics of the individual that play a role in the development of victimization or bullying behavior (e.g., the child's temperament). The second level of the model focuses on an individual's interpersonal

relationships (i.e., with their family or friends) and how these may heighten the risk of being victimized or engaging in bullying behaviors. This could include factors such as parenting style (e.g., Baldry & Farrington 2000) and friendship relationships (e.g., Cairns et al., 1988; Pellegrini et al., 1999). The third level of the model examines the community and more precisely the schools and neighborhoods as an ambience in which interpersonal relationships happen and how each of them relate to the risk of victimization or bullying behaviors. The identified risk factors in this level may encompass social circumstances (e.g., the caregivers being of no fixed abode, frequent relocations of the family, and living within a heterogonous population) and economic factors (e.g., high levels of unemployment, likelihood of witnessing crime in terms of getting involved in gangs, guns and drug-dealing activities). Thus, the last mentioned characteristics of an immediate community can penetrate into school communities and act as encouragement for violent attitudes and behaviors. The fourth and last level of the ecological model considers the wider societal factors that may affect the rates of violence. These include the established social and cultural norms supporting violence as an acceptable way of conflict resolution or a solution to a political conflict, undermining child welfare and giving priority to parental rights within a family home and possibly putting the child in danger and supporting male dominance over women and children.

Other societal factors, such as the educational, economic and social policies responsible for the economic or social inequality between groups in society, can also be included at this level (Askew 1989; Carter 2002; O'Moore, Kirkham & Smith 1997).

A lot of research investigating cyberbullying is not theoretical and tends to examine the phenomenon from only one perspective (i.e., victim). Research investigating teachers' perceptions of the cyberbullying phenomena and the importance of safety and support in schools and the effect of these issues on their psychological well-being is presented in this chapter. As the academic interest in bullying has been maintained in the UK since the late 1980s, it was assumed that UK teachers have an awareness of the cyberbullying phenomenon, that they are likely to perceive it as a problem at school, that they were aware of the known effects of cyberbullying on adolescents' well-being, and that they felt confident to deal with cyberbullying incidents if they occurred on school premises.

METHODS AND FINDINGS

This research commenced in 5 different schools from the West Midlands region in England. Twenty-eight teachers [18 females (64%) and 10 males (36%)] participated in semi-structured interviews. The interviews were analyzed using thematic analysis, a flexible and useful tool which can potentially provide a rich, detailed, and yet complex, account of data (Braun & Clark 2013). Thus, the thematic analyzing process, as suggested by Braun and Clarke (2013), began by reading through the answers to the open-ended question and giving interesting features initial codes. The encoding requires an explicit "code." A theme is a pattern found in the information that at the minimum describes and organizes the possible observations or at the maximum interprets aspects of the phenomenon. A theme may be identified at the manifest level (i.e., directly observable in the information) or at the latent level (i.e., categorizing issues underlying the phenomenon). A code may be a list of themes; a complex model of themes, indicators, and qualifications that are casually related or something in between these two forms.

A codebook is the compilation or integration of a number of codes in a study. The coding process can briefly be described in two steps: (a) open coding and (b) selective coding. In the open coding process, the interviews were analyzed line by line and broken down into segments reflecting the substance of the data, i.e., the emerging themes. The themes with the same content were grouped together to form more abstract themes. From their accounts, seven codebooks were identified. The codebooks included Internet, Perspicacity, Seen through the eyes of bystander, Threat to self and well-being, Readiness to act, Avoidance and Support (see Table 1).

Table 1. Codebooks with identified main themes and subthemes

	Main themes	Subthemes
	Use	-Educational -Personal
	Access to medium	-Improvement -Hindrance
	Understanding of the phenomenon	-Personal experience -Means -Medium -Technique
	Beliefs about cyberbullying	-Reasons -Dangers -Characteristics
	Consequences for cyber-victim	-Threat to own health -Threat to social life
	Consequences for cyberbully	-At school -In personal life
	Action taken by cyber-victim	-
	Action taken by teacher/ school	-School staff involvement -Organizational characteristics
	Action taken by peer	-
	Cyberbully	-Social immaturity -Emotional disturbance -Lack of perspective taking
	Cyber-victim	-
	Avoidance in accessing support	-
	Factors preventing problem solving	-
	Support	-

The *Internet* codebook, which emerged through the data analysis focused on participants' views in terms of the Internet and the risks and opportunities associated with its use by young people, was linked to three out of the four layers of the ecological model. Results presented in the *Internet* codebook confirmed the increased popularity of Internet-related technologies among young people, with participants commenting on two main reasons for using the net: (a) educational purposes and (b) personal purposes. The educational reasons for using the Internet-related technologies included finding information for school projects, and doing homework.

“We have MyMaths which is a system where students do homework through the internet.” Teacher #8.

The personal reasons for using the Internet-related technologies consisted of continuing communication with friends after schools using social networking sites as well as other activities, such as downloading music or videos, online shopping and gaming. These functions were reflected by one teacher in the context of acceptable Internet-related technologies:

“I think that the use of the internet for students now is predominantly to do with social accepted, or acceptable social networking sites, particularly Facebook.”, Teacher #6.

UK teachers also commented on the differences in terms of access to the Internet that they have noticed in the recent past. They highlighted that the access to internet has improved whilst taking into consideration other aspects, such as speed of connection, price, the amount of the equipment available for use, advances in technology, more products becoming easily accessible on the market, and increased parental awareness of the benefits of Internet and computer. Some teachers reflected on how the usage of technology at home has exploded in recent years.

“I would say it’s really mushroomed in the last three years using the internet I wouldn’t be sure how many of our children would have had access to it prior to that.” Teacher #3.

“It’s more affordable, more parents use it at work so, more parents are aware of internet so you know it’s in more homes now.” Teacher #5.

Moreover, despite noticing so many advantages of computer and Internet use, UK teachers also commented on issues which could still be improved.

“Now we have cuts [loss of connectivity] for very short term in school when the internet goes down.” Teacher #8.

“Now it’s fast you just google whatever you want and there it is. It’s not true everywhere but it’s very good here at school. At my house it’s hopeless because I live out in the countryside, out in the sticks as we call it, and a lot of children live in the sticks too and they will have it very slow as well.” Teacher #18.

Linking the findings presented in the *Internet* codebook with the ecological model of cyberbullying, we suggest that the Internet can be seen as part of the macrosystem (in terms of the wider society factors), which permeates throughout all other layers of the model. Internet-related technologies allow for interaction between individuals, families, schools, and workplaces, and this interaction affects young people’s development. Young people learn how to use technological devices, such as mobile phones or computers, for educational and personal purposes. This impacts the microsystem layer in terms of young people gaining new skills. Young people use social networking sites to sustain relationships with their peers outside of the school environment. They often face parental restrictions on the duration of mobile phones, computers, and Internet use, and they have to cope with sharing the available technologies with their siblings. With time, they gain parental trust to use these Internet-related technologies for basic or school related activities. Hence, the Internet, as part of the macrosystem, affects the

mesosystem layer (e.g., different communication styles, methods of recreation, changes to relationships with siblings and parents), and exosystem layer (e.g., changes to the learning environment).

The *Perspicacity* codebook focuses on the participants' understanding of and beliefs regarding cyberbullying. This section is broken down into two main themes; the first describes the knowledge that teachers had gained regarding the issue of cyberbullying through personal experiences of dealing with cyberbullying incidents or observing one's colleagues managing such incidents. Moreover, this theme showed that UK teachers were aware of how and via which means cyberbullying can be perpetrated, as elaborated by one teacher:

"We've had incidents where...for instance inappropriate photos have been taken at a party, and these have been circulated that's happened on Facebook and on mobile phones."
Teacher #3.

In addition, this theme also emphasized that the UK teachers were able to specify some features of cyberbullying that they have seen or heard about, of which these behaviors were specified in the definitions proposed by scholars. They spoke about cyberbullying taking place during and outside of school, perpetrators' ability to be anonymous, the likelihood that the behaviors can reach a wide audience, and how such behaviors typically involve aggressive language. A teacher reflected on each of these components in the interview:

"I think it's because it's easy, it's much easier than going to somebody face to face and risking being punched in the nose or having something back at you, 'cause even through a computer screen even if somebody is responding to you, you are a step removed from it and it doesn't feel real, does it. It's like a game playing etc. and it's an association that it's not a real world it's a fantasy world." Teacher #14.

Aggressive language was mentioned by participants as one of characteristics of cyberbullying. This finding seemed to support the suggestion of Ybarra et al. (2006) that the content and tone of a message determines if a communication is classified as cyberbullying. UK teachers highlighted that the messages written could at times be ambiguous and difficult to interpret. It may be beneficial to explore this use of language further with young people in order to understand it more fully. A teacher focused on the difficulty of evaluating cyberbullying incidences, especially when teachers cannot understand the language being used:

"We were decoding language that we didn't even understand, we had to ask people what does that mean, 'cause it was like a street talk, I didn't understand it." Teacher #7.

UK teachers viewed cyberbullying as a social activity because communicating via social networking sites is widely popular and an accepted way to communicate among teenagers. Thus, it can be assumed that UK school staff perceive cyberbullying as an issue taking place not only within students' home environment.

The Threat to self and well-being codebook focused on the seriousness of cyberbullying in terms of its impact on students' health and well-being. Feeling stressed and experiencing stress-related physical health problems, feeling low in mood and/or suicidal, and engaging in self-harming behaviors were the consequences of cyber-victimization mentioned by UK teachers. Moreover, they also spoke about the impact of cyberbullying on victims' mental health, with

victims developing depression and eating disorders, and they also referred to the impact on cyber-victims' emotional state, school attendance, and school performance. The following reflects teachers' perceptions of the impact of cyberbullying on victims:

"He gets really frustrated and angry, he comes down to our area and he punches everything possible. He doesn't think anything has changed; this stigma will always stay with him about what these lies have said. And he deals with it in this particular moment he deals with it through anger, he gets really crossed, he shouts and hits things but doesn't hurt anybody else just himself." Teacher #5.

"He got ill, he got stressed, he got mentally ill because he's got very scared he did not want to think about coming back to college in case he would come across her physically, so you know it was more of emotional illness rather than physical but he just got very stressed and upset." Teacher #25.

"One aspect is the student who is being bullied losing confidence and either becoming an attendance issue, we haven't any at the moment but we have students who had an attendance issue." Teacher #8.

Finally, within this codebook, UK teachers reported a factor which has not, to date, been considered in the research literature. These responses focused on the impact of cyberbullying on young people who perpetrate this behavior. The participants highlighted that cyberbullies face a number of consequences at school as well as issues at home in terms of parents imposing restrictions on cyberbullies' access to the Internet.

"There was one student was put in pit, it's an isolation room so he spent a day in a room, they stay there for all the lessons, lunch and break. There is a member of staff in there but they just sit at the table and get on with their work." Teacher #15.

In addition, the participants also discussed the long-term consequences for cyberbullies in terms of the difficulties they may face in adult life with regard to seeking employment whilst having a criminal history record.

"The bully sees the consequences of their behavior the lasting effects of their behavior can be very similar because it can affect their life chances, they can start having difficulties with the police and so on." Teacher #19.

The *Readiness to act* codebook combined methods for preventing and addressing cyberbullying issues in schools and managing cyber-victimization by the victim and victims' peers who had knowledge of the event. A whole school community approach was considered to be required and the need to involve pupils, staff, other schools, parents, and the wider community was highlighted. UK teachers spoke about cyber-victims' access to support from their friends, confronting the perpetrator, retaliating, and seeking support and advice from others, such as their parents, older siblings, and school staff.

"Other students informed me and the girl came to see me because this young man is in my tutor group and people know that he has learning difficulties as well. He is known around college as doing inappropriate things and other students told me about it." Teacher #5.

“He actually went to his tutor and told him about it a little while after, it’s gone on for a few weeks so then he actually went to the tutor and told the tutor.” Teacher #25.

These findings concur with the ways of coping with cyberbullying experiences as identified in the literature. Research indicated that cyber-victims tend to use technological coping strategies, such as changing privacy settings (e.g., Aricak et al., 2008; Juvonen & Gross 2008), user names (e.g., Juvonen & Gross 2008), or email addresses (e.g., Smith et al., 2008) as ways to prevent further cyber victimization. Other active coping strategies employed by young people included confronting cyberbullies (e.g., Aricak et al., 2008; Juvonen & Gross 2008; Patchin & Hinduja 2006), informing parents or other adults about being cyberbullied (e.g., Aricak et al., 2008; DeHue et al., 2008; Slonje & Smith 2007), and consulting friends for advice (e.g., Aricak et al., 2008; DeHue et al., 2008; Slonje & Smith 2007). UK teachers highlighted the measures employed within their workplace to prevent and manage cyberbullying incidents. They spoke about advising students in terms of preventing further cyber-victimization and putting emphasis on the importance of not using whichever platform cyberbullying was taking place.

“I mean you can switch it off, and ultimately that’s our advice, you switch it off, people always I suppose it’s something of use as well I’ve known grown- ups act the same that you worry what people are saying behind your back I think you have to learn not to worry ‘if you can’t hear it it’s not happening’ is my attitude you know. So, my advice to people is to switch off their Facebook don’t let it happen, block people, you don’t have to choose to be complacent in that.” Teacher #3.

Moreover the findings within this general theme also highlighted that school staff had considered their responses to cyberbullying incidents in both proactive (e.g., teachers attending training focusing on cyberbullying, holding regular school assemblies for students to disseminate knowledge about cyberbullying) and reactive terms (e.g., contacting parents of students’ involved in an incident as well as police, other agencies, or professionals). UK teachers also reported focusing primarily on policy development and training for students, school staff, and parents, and declared that working with students on developing their understanding of how to stay safe online and what behaviors constituted cyberbullying.

“I think certainly with the Facebook stuff we get a lot of parents complaining this has happened on Facebook that has happened on Facebook, we try to speak to parents a lot about that and what they can do to stop that happening.” Teacher #3.

“We do intra training, not actually for staff, but we do like advice evenings where we are getting people like from Barnardos to talk to parents about how to protect children as well.” Teacher #3.

Although a mobile phone ban was discussed by UK teachers as a possibility, they felt that it would not solve the problem of perpetrating cyberbullying behaviors. Thus, the results showed a differing reaction to new Internet technologies available in schools, with some educational establishments choosing to ban mobile phones and others highlighting that this would not be realistic due to the amount of technology which is used within the schools. This latter view seems to support the suggestion of the Byron Report (2008), which indicated that,

rather than viewing technology as causing harm, it would be beneficial to equip students with skills allowing them to remain safe in the digital world. It could, therefore, be argued that rather than banning technology on school premises, a greater emphasis should be placed on using the equipment responsibly with support from staff.

The *Seen through the eyes of bystander* codebook described a cyber-victim and a cyberbully as perceived through the eyes of others. UK teachers believed that words such as shy, lonely, and companionless provide an accurate description of a cyber-victim. Participants also agreed on a number of negative features which characterize a cyberbully. These portrayed cyberbullies as lacking an understanding of the impact of their behavior and which the behaviors cyberbullies perceived as normal. Previously reported findings suggested that a factor in cyberbullying behavior may be the impersonal nature and the anonymity offered by the medium, resulting in bullies not understanding the consequences of their actions – a factor which would also appear to be supported by findings reported in the *Perspicacity* codebook (Englander & Muldowney 2007).

“Because it is so easy for them to do it through a screen. I think sometimes the students don’t realise how much hurt it causes when they do it via a screen. They just put their thoughts down without thinking about the consequences whereas they’d never actually say that to that person’s face or they don’t understand how people could be upset by it. I think they’re too much in this virtual world sometimes and they just forget about the real consequences unfortunately.” Teacher #12.

UK teachers also indicated that perpetrating cyberbullying may be used as a maladaptive coping mechanism, fulfilling a need to feel in control or to attract attention if the perpetrator had difficulties coping with problems at home.

“I think it’s quite complicated about the reasons why people would do it but generally I think it’s a sense of having to one over somebody else or being able to manipulate somebody else and the sense of power that comes with it.” Teacher #14.

Therefore, school staff could play an important role when working with students to enable them to understand the real emotional and psychological impact cyberbullying can have. As dealing with such issues in a school context required considerable tact and discretion, future research should consider how these incidents could be dealt with most effectively in the future.

The *Avoidance* codebook focused on exploring reasons why young people tend not to report being cyberbullied. These have been divided into two main groups: (a) reasons for avoiding reporting cyber-victimization, and (b) factors for preventing effective problem-solving, which in turn could impact victims’ readiness to act in such circumstances. Doing nothing in response to being victimized has been infrequently employed by victims (Patchin & Hinduja 2006). In terms of cyberbullying, this may be more complex, as current findings suggest that students are reluctant to report cyber-victimization to teachers, parents, or police for fear of retribution from the bully and other students. Previous research indicated that school staff were the least chosen adults to report cyber-victimization to (Kowalski et al., 2008; Slonje & Smith 2008). Young people’s reluctance to approach parents or teachers for support (presents an interesting conundrum in the literature (Kowalski et al., 2008; Marczak 2014; Slonje & Smith 2008). In theory, positive family relationships and the ability to seek and receive support from adults should help young people deal with difficult situations. However, UK teachers

highlighted that young people may not want to seek help hoping that they would be able to manage it themselves or may be afraid of the adults' reaction.

"Although quite interestingly enough a lot of students don't want to tell their parents because they know perfectly well that they have been involved in it themselves when someone called them names or whatever." Teacher #6.

"They seem to be reluctant to seek help at the early stage, they seem to just want to put it off and deal with it themselves, don't want to tell anyone." Teacher #24.

"They are probably scared of talking about it because they are scared of looking like this person who is talking to a teacher, you know like telling the teachers they may look a bit wet or something so they may be scared of telling us." Teacher #28.

Therefore, if schools are expected to become involved and work collaboratively with parents in managing cyberbullying incidents, they would have to do so very carefully. Furthermore, findings suggest that there is a real possibility of students being confused about who to approach should such incidents occur. They might also not be confident that others are able to help them. This is an area which requires significant consideration from parents, school staff, and young people themselves, particularly given the fact that schools are already struggling with the increases in workload in terms of the national curriculum and the lack of time to teach.

The *Support* codebook focused on suggestions made by UK teachers, which they would like to be employed within schools and their wider communities. Their hope is that this information can be used to further cyberbullying prevention and management. Having a designated member of staff who deals specifically with cyberbullying incidents, having access to more information or training on e-safety (which would include cyberbullying), and raising parents' awareness of this phenomenon were commonly reported in the interviews.

"We educate students, maybe we could do more with parents. We had two parents invitation evenings in the last 5 years for when we've had internet bullying people presenting. In the first night we've had four parents and then in the follow up we've had six parents out of about 500 students so a 1000 roughly parents." Teacher #8.

UK teachers wished for further direction from the central government on managing cyberbullying incidents by school staff and ISPs to act more responsibly by way of monitoring online traffic.

"I think, maybe this is on a magical wish list but what I really want to see is some direction from the central government to give legal clarity as to what we can and can't do. We've recently had clarity from the government in conjunction with the police about dealing with drug related incidents, very clear guidelines. With regards to bullying it's, cyberbullying is still attached to your bullying policy which we have and all schools have." Teacher #6.

This highlights difficulties faced by UK teachers when managing cyberbullying incidents. The presented above results also highlight the implications of cyberbullying in terms of safeguarding students in the schools and the barriers encountered by staff in order to be able to

carry out this function and a need to involve the wider community for successful management of cyberbullying incidents.

DISCUSSION

These findings highlight that raising awareness among adults needs to continue. Adults (i.e., school staff and parents – representing the exosystem and the mesosystem in the ecosystemic framework) are responsible for creating environments in which young people's capacities and competencies for healthy relationships can be promoted and in which opportunities for negative peer interactions are minimized (Craig & Pepler 2007). When adults are aware of young people's interpersonal interactions, they can help them protect themselves against cyber-victimization, seek support during a cyberbullying incident, and minimize the re-occurrence of cyber-victimization. However, to be able to do this, young people need to understand that cyberbullying is not just a school staff problem and that parental involvement together with help from the wider society (statutory and regulatory organizations, representing the macrosystem) are essential requirements of intervention programs.

Bronfenbrenner's (1979) theory of ecological systems provides a framework for conceptualizing cyberbullying. It states that human development is affected by several ecological systems. Bronfenbrenner's model has been adapted to explain a wide range of social problems, such as childhood obesity (e.g., Opalinski 2006), and postpartum depression (e.g., Garfield & Isacco 2009). Bronfenbrenner's model has also been adapted by the World Health Organisation (1999; 2002) to understand the multiple causes of aggressive behavior. Moreover, it also has been used by Swearer and Espelage (2004) to explain traditional bullying, which is a result of complex interactions between individual factors and social environments (i.e., family, peers, school, community, culture).

The ecological model proposed in this chapter consists of four interrelated systems, encompassing a number of factors or events with regards to cyberbullying, cyber-victimization, and cyberbullying prevention and management. The four systems include:

- the microsystem - individual characteristics of cyberbully and cyber-victim, such as age, gender and individual differences that increase the likelihood of being a cyberbully or a cyber-victim;
- the mesosystem - interpersonal relationships such as parent-child relationships, home difficulties, and peer relationships, and associated social support;
- the exosystem - school community context such as school environment, school climate, and teacher-student relationship;
- the macrosystem - wider society, such as cultural norms and beliefs, media portrayal of violence, media industry, usage of IT for educational and personal purposes, access to mediums, community environmental factors, and intervention programs.

Micro, meso, exo, and macro systems all interact with each other from the beginning of a child's life. This begins with the family house, and then extends to those factors influencing the child outside of the home. According to this model (i.e., Bronfenbrenner 1975), the growing

child is affected by the immediate surrounding environments, adult and peer interactions, and later on societal influences as well as the interactions between these environments.

MICROSYSTEM - LEVEL 1: INDIVIDUAL CHARACTERISTICS OF THE CYBERBULLY AND CYBER-VICTIM

The first level of the model focuses on individual characteristics, such as such as one's personality, behavior, and motives. Individual factors of the young person will impact on his or her involvement in cyberbullying. Participating teachers listed a number of characteristics that, in their opinion, describe the cyber-victim and the cyberbully. They agreed that in terms of a cyberbully these characteristics included a lack of empathy, perspective taking skills, and using maladaptive coping strategies to deal with problems. A cyber-victim was, on the other hand, perceived as quite a lonely and introverted person, outside of a peer group, not willing or not able to defend oneself, and would not retaliate. In addition, UK teachers spoke about young people having better access to the Internet and their increased ability to use it for longer periods of time as well as for different activities. Whilst the lack of knowledge in terms of securing passwords or appropriate privacy settings highlights the need for further IT training for young people in terms of cyberbullying prevention, the use of maladaptive coping strategies on behalf of the cyberbully shows more needs to be done to support the perpetrator in terms of developing pro-social skills. Moreover, these results suggest show that the level of knowledge and understanding of cyberbullying has increased among young people and their teachers.

Mesosystem - Level 2: Interpersonal Relationships

The second level of the model focuses on an individual's interpersonal relationships (i.e., with their family or friends) and how these may heighten the risk of being victimized or engaging in bullying behaviors. They, therefore, included parent-child relationships and possible family home difficulties (e.g., parental divorce, parental violence), and negative or positive peer relationships. The child's individual characteristics (one microsystem), family home (one microsystem), and the peer group (another microsystem) interact together creating a mesosystem.

Regarding the family context, UK teachers explained that cyber-victims may be afraid of their parents' reaction as it may lead to further consequences being imposed by the parents. They had the opinion that victims' decision to inform their parents would depend on the relationships within the family home. They felt that more positive parent-child relationship would encourage children to talk to the parent about a cyberbullying incident.

In relation to the mesosystem layer of the model and cyberbullying, these findings are interesting as they imply that young people choose to confide in each other as they can rely on sufficient and effective support from their peers. This needs to be carefully monitored, as Kowalski et al. (2008) suggested that if school staff do not respond to the incidents, this can lead to students having less empathy for the cyber-victim. Moreover, as increasingly more young children are involved in cyberbullying, the possibility exists that the social skills necessary to support their peers when needed may not be sufficiently developed.

EXOSYSTEM - LEVEL 3: COMMUNITY CONTEXT

The third level of the model examines the community setting and more precisely the schools and neighborhoods as an ambience in which interpersonal relationships happen. These settings include the school environment, which may include school-related stressors, school atmosphere in terms of tolerating cyberbullying, teachers' approach to inappropriate behaviors in terms of reinforcement of anti-bullying and behavioural policies and received training, as well as the relationships between teachers and students in terms of reporting the incidents.

The Exosystem involves understanding the inter-relations between Level 1 (microsystems) and Level 2 (mesosystems). The parental reaction to the news that their child is a cyber-victim or a cyberbully can create an exosystem, if that parent is contacted by the school with regards to the incident or decides to contact the school when the child confides in him or her. Ybarra and colleagues' (2007) research revealed that schools find it difficult to select the right approach to manage cyberbullying incidents when parents approach the school with a complaint that their child is a cyber-victim or cyberbully. The reason for this difficulty was that cyberbullying often takes place outside of the school grounds, when the victim is at the family house, but the individuals involved in the incidence usually involve pupils from the same school.

UK teachers also highlighted that young people may engage in cyberbullying to raise his or her own status within the peer group. This finding concurs with Andreou, Didaskalou and Vlachou's (2008) results, highlighting that whilst bullies usually act on his or her own, the behavior is reinforced and encouraged by the peer group. Therefore, any interventions and prevention strategies should be directed not only toward the perpetrator but to the whole peer group and school community to improve the school climate.

Findings from the presented study highlight a number of changes that took place within the school environment (i.e., the exosystem). These included implementing some cyberbullying preventative strategies within the school (i.e., netiquette training, anti-bullying awareness week, school assemblies) aiming to raise students' awareness of this phenomenon.

With regards to having parental involvement in cyberbullying incidents, UK teachers spoke about struggling with parental attendance at specially organized parents' meetings during which either themselves or professionals from outside agencies spoke about cyberbullying. UK teachers also emphasized the importance of the whole school community involvement in cyberbullying prevention and management.

MACROSYSTEM - LEVEL 4: WIDER SOCIETY

The fourth and the last level of the ecological model considers the wider societal factors that may affect the rates of aggression. They may determine social structures and activities that occur at Level 1 and 2, and include aspects of the environment beyond the immediate system containing the individual. Though this system may not directly involve the individual, it may affect the ways in which young people interact with others in Level 2. This system encompasses cultural norms and the beliefs held within society, the media's portrayal of cyberbullying, technological industry, community environmental factors, and intervention programs.

Findings from teachers suggest that they would deal with cyberbullying similarly regardless of if they had direct experiences. Regardless of the level of experience, UK teachers were aware of incidents involving students from their school. Moreover, whilst UK teachers were able to follow the school's anti-cyberbullying policy, they saw the need for further guidance from policy makers on how to manage cyberbullying incidents. UK English teachers spoke about attending special workshops or training events which broadened their knowledge of the cyberbullying phenomenon. Thus these findings also show the working objective of the statutory and voluntary organizations with regard to promoting e-safety, netiquette, changes to curriculum, dissemination of knowledge through a variety of means, which included organization and attendance at conferences, e-safety programs, and media campaigns.

CONCLUSION

Sparse research has been conducted on cyberbullying prevention and intervention (Grigg 2010), although a whole school approach is seen as imperative. Both preventative and management strategies should ideally combine as many ecological systems as possible to help reinforce the message that whether it is traditional school bullying or cyberbullying, such behavior is wrong and should be avoided. In accordance to the Ecological Systems Theory (Bronfenbrenner 1979), it is of paramount importance that students, school staff, parents, and the wider community work together in order to develop and implement multi-level strategies to deal with cyberbullying.

Chapter 13

EXPOSURE TO ANTISOCIAL AND RISK BEHAVIOR MEDIA CONTENT STIMULATES CYBERBULLYING BEHAVIOR: THE CYCLIC PROCESS MODEL

Anouk den Hamer* and Elly Konijn

VU University Amsterdam, Dept. of Communication Science, Section Media Psychology

INTRODUCTION

Ten years ago, cyberbullying behavior, or bullying carried out via electronic media, was a relatively new phenomenon (Smith, 2014). Over the last ten years, research investigating cyberbullying has accumulated rapidly. At first, the majority of research was descriptive in nature and scholars tried to determine how many children and adolescents were victims of cyberbullying or cyberbullies themselves. Results showed that cyberbullying peaks during adolescence and between 10% to 40% of adolescents have been a victim of cyberbullying (Kowalski, Giumetti, Schroeder, and Lattanner, 2014; Tokunaga, 2010). Much research has focused on the negative impact of cyberbullying and how victims cope with it. For example, being victimized through cyberbullying relates to a number of psychosocial difficulties, such as depression, anxiety, and stress (e.g., Campbell, Spears, Slee, Butler, and Kift, 2012; Gamez-Guadix, Orue, Smith, and Calvete, 2013; Gradinger, Strohmeier, and Spiel, 2009; Wang, Nansel, and Iannotti, 2011), suicidal ideation (e.g., Bauman, Toomey, and Walker, 2013; Hay and Meldrum, 2010; Hinduja and Patchin, 2010; Sinclair, Bauman, Poteat, Koenig, and Russel, 2012), and poorer academic achievement (e.g., Kowalski and Limber, 2013; Sinclair et al., 2012). Furthermore, numerous studies have showed that having been victimized by offline or online bullying is related to being or becoming a cyberbullying perpetrator (Bauman, 2010; König, Gollwitzer, and Steffgen, 2010; Kowalski, Morgan, and Limber, 2012; Patchin and Hinduja, 2011; Smith, Mahdavi, Carvalho, Fisher, Russel, and Tippett, 2008; Sontag, Clemans, Graber, and Lyndon, 2011; Wong, Chan, Cheng, 2014; Wright and Li, 2012; Wright and Li, 2013; Ybarra and Mitchell, 2004; Yilmaz, 2011). The relationship between being victimized (i.e., being bullied) and becoming a cyberbully is striking because one might expect that these

* Corresponding Author's Email: a.h.den.hamer@vu.nl.

victims understand the impact of being bullied and would not harm others in such an unpleasant situation. Therefore, we investigated the underlying processes that take place in the relationship between victimization and cyberbullying behavior.

In the current chapter, we provide arguments for a Cyclic Process Model as a framework to investigate the relation between being bullied and becoming a cyberbully. To clarify this relationship, the Cyclic Process Model proposes that victimized adolescents get angry and frustrated, which draws them to media with antisocial and risk behavior content, further easing the way to become a cyberbully. Thus far, the role of adolescent media use in this chain of events has been understudied. Therefore, our research focused on the role of media use in cyberbullying behavior. In the following section, we first provide a short overview of the current state of cyberbullying research. Next, the role of media in cyberbullying behavior is discussed and the Cyclic Process Model is introduced. In addition, we provide empirical tests of the Cyclic Process Model with different samples showing the underlying, amplifying role of media use. The chapter concludes with a summary of the findings, limitations, and challenges in view of future research.

PREVALENCE AND DEFINITION OF CYBERBULLYING

Prevalence rates of cyberbullying involvement vary substantially among studies, which is mostly due to a mix of factors (Kowalski et al., 2014; Modecki et al., 2014; Smith, 2014). One factor leading to different prevalence rates is the use of different measurement instruments. For instance, some researchers use a specific time frame when asking their respondents how often they perpetrated acts of cyberbullying (e.g., in the past year or the past six months; Campbell et al., 2012), while others do not mention a time reference period and measure “lifetime” victimization (Calvete et al., 2010). Prevalence rates obtained by lifetime measurements are often higher than prevalence rates in which the timeframe was restricted (Kowalski et al., 2014). Furthermore, prevalence rates of cyberbullying are lower in samples where the word “bullying” is used in the measurement instrument (e.g., “how often did you bully someone in the past 2 months?”) than in samples where the word “bully” is not mentioned (Kowalski et al., 2014; Modecki et al., 2014). This is possibly due to social desirability in responding to questions (Kowalski et al., 2014) because respondents probably do not want to associate themselves with the term “bully,” either as a victim or a perpetrator.

Another factor that affects the prevalence rates is the frequency criterion. Some researchers classify cyberbullying behavior when someone has cyberbullied someone only once, while others classify cyberbullying when it occurred on a frequent basis. This frequency criterion is related to repetitiveness. This criterion is linked to the literature on traditional (or offline) bullying, in which three key criteria are defined for bullying behavior: a) the bully’s intention to harm (intentionality), b) the bullying happened on multiple occasions (repetitiveness), and c) the victim finds it difficult to defend him or herself (i.e., power imbalance) (e.g., Olweus, 2013; Smith, del Barrio, and Tokunaga, 2013). In the last few years, the criterion of repetitiveness in view of cyberbullying has been discussed among various scholars (e.g., Dehue, 2013; Langos, 2012; Menesini et al., 2012; Olweus, 2013; Slonje et al., 2013; Smith et al., 2013) because online a single act of cyberbullying behavior can last forever and lead to ongoing embarrassment. Therefore, some researchers suggest that the criterion of repetitiveness

is subsidiary to defining cyberbullying behavior (Menesini et al., 2012; Smith et al., 2013), while the most important criteria are: a) the intent to harm, b) the existence of a specific target, and c) an imbalance of power between perpetrator and victim (Smith et al., 2013).

The definition which, in our opinion, describes cyberbullying best, is the definition of Langos (2012). According to Langos, cyberbullying behavior “involves the use of ICTs to carry out a series of acts as in the case of direct cyberbullying, or an act as in the case of indirect cyberbullying, intended to harm another (the victim) who cannot easily defend him or herself” (p. 288). Here, intentionality, the existence of a specific target, and the power imbalance are explicitly described, while repetitiveness is only included in direct cyberbullying. Direct cyberbullying involves direct contact between perpetrator and victim. The direct cyberbullying has to occur on repetitive occasions, because it could otherwise be “teasing” or “joking around” as perceived by the victim. On the contrary, indirect cyberbullying happens when acts of cyberbullying are distributed on, for instance, social networking sites. Based on this definition, the repetitiveness of the cyberbullying act itself is not a prerequisite, since the cyberbully incident can stay online forever and be seen by many over and over again. We support the definition of Langos, because it covers the key criteria for bullying behavior and we also acknowledge that the act of bullying in cyberspace does not have to occur on multiple occasions to lead to repetitive humiliation. Following the above considerations, it is important to know which methodologies and definitions are applied in order to interpret a study’s prevalence rates of cyberbullying. Another important factor influencing prevalence rates is age, or rather age groups or developmental stage.

ADOLESCENTS’ INVOLVEMENT IN CYBERBULLYING BEHAVIOR

In the last five years, various meta-analyses and reviews of the extant research described the state of cyberbullying research (e.g., Hinduja and Patchin, 2012; Kowalski et al., 2014; Modecki, Minchin, Harbaugh, Guerra, and Runions, 2014; Slonje, Smith, and Frisen, 2013; Tokunaga, 2010) and reported that between 10-40% of adolescents have been victims of cyberbullying (Kowalski et al., 2014; Tokunaga, 2010). As for perpetrators of cyberbullying behavior, the average percentages of cyberbullying perpetration among adolescents are somewhere around 16% and 17% (Hinduja and Patchin, 2012; Modecki et al., 2014). While some cyberbullying research has been conducted among adults (e.g., in an Australian study among 103 working males, 10.7% had been a victim of cyberbullying; Privitera and Campbell, 2009), the majority of studies focused on children and adolescents. Cyberbullying clearly peaks during adolescence, notably around the age of 12-14 (Kowalski et al., 2014; Slonje et al., 2013; Tokunaga, 2010). Therefore, we decided to focus our research on cyberbullying behavior among adolescents.

Overall, cyberbullying (still) occurs less often than traditional face-to-face (or offline) bullying, yet these bullying types are highly correlated. In particular, individuals who are bullied offline are often also bullied online, and perpetrators often bully both offline and online (Kowalski et al., 2014; Modecki et al., 2014; Slonje et al., 2013). Furthermore, a summary of 131 quantitative studies showed that performing acts of cyberbullying is related to being a victim of cyberbullying ($r = .51$) and being a victim of offline bullying ($r = .21$; Kowalski et

el., 2014). Hence, why this relationship exists, or why victims may become bullies themselves, is an important question that seems unanswered thus far.

Furthermore, research on gender differences in cyberbullying behavior have provided mixed results (Kowalski et al., 2014; Slonje et al., 2013; Tokunaga, 2010). Some studies have found boys to be more likely to be cyberbullies (e.g., Calvete, Orue, Estévez, Villardón, and Padilla, 2010; Fanti, Demetriou, and Hawa, 2012), while other studies show that girls were more often cyberbullies than boys (e.g., Kowalski and Limber, 2007), and yet other studies did not find gender differences in cyberbullying behavior (e.g., den Hamer and Konijn, 2015; Hinduja and Patchin, 2008; Lonigro, Schneider, Laghi, Baiocco, Pallini, and Brunner, 2014; Smith et al., 2008).

In our own research, we found rather high prevalence rates of cyberbullying perpetration. For example, in our cross-sectional study, 48.4% of boys and 36.0% of girls have cyberbullied someone (den Hamer, Konijn, and Keijer, 2014). In our longitudinal study, 33.5% of boys and 24.4% of girls had ever performed acts of cyberbullying (den Hamer and Konijn, 2015; den Hamer, Konijn, and Aartsen, under review-a). We measured cyberbullying behavior using the often applied Cyberbullying Questionnaire (CBQ; Calvete et al., 2010), which we updated according to modern smartphone technology and use with adolescents (den Hamer et al., 2014). We applied a “lifetime” framing reference, thus asking participants (i.e., adolescents) if they had ever performed certain cyberbullying behavior, such as sending hurtful messages through e-mail or mobile phone, or broadcasting other people’s secrets online. Participants could indicate whether they never, incidentally, several times, often, or very often performed this behavior. The word “bully” was not mentioned in our questionnaire, although probably all participants understood that the survey concerned cyberbullying. While these prevalence rates are based on a frequency criterion of ‘happened once or more often’, all relational and predictive analyses were conducted using a continuous scale of cyberbullying (1 = *never* to 5 = *very often*). Detailed information on the methodologies can be found in den Hamer et al. (2014), den Hamer and Konijn (2015), and den Hamer et al. (under review-a).

In sum, cyberbullying behavior occurs mostly among adolescents, among both boys and girls, and involves an overlap between offline and online bullying. An important question that arises from the overlap between victims of bullying behavior and being a bully oneself, is what factors underlie becoming a cyberbully.

BECOMING A CYBERBULLY

What leads a youngster to becoming a cyberbully? Research has showed that several characteristics predict cyberbullying behavior. One of the most common motives for cyberbullying is anger (Gradinger, Strohmeier, and Spiel, 2012; Lonigro et al., 2014; Patchin and Hinduja, 2011). Other known predictors of cyberbullying behavior are being an offline bully (e.g., Fanti et al., 2012; Modecki et al., 2014; Perren and Gutzwiller-Helfenfinger, 2012; Sticca, Ruggieri, Alsaker, and Perren, 2013), low levels of empathy (Ang and Goh, 2010; Steffgen, König, Pfetsch, and Melzer, 2011), and high levels of narcissism (e.g., Ang, Tan, and Mansor, 2011). However, not much is known about the chain of events that lead to performing acts of cyberbullying behavior (Slonje et al., 2013). Some researchers suggest that some adolescents perform acts of cyberbullying because they are victims of bullying themselves

(offline or online; Slonje et al., 2013). Indeed, the link between victimization and being a perpetrator of cyberbullying is supported by many studies (e.g., Ak, Özdemir, and Kuzucu, 2015; Bauman, 2010; König et al., 2010; Kowalski et al., 2012; Patchin and Hinduja, 2011; Smith et al., 2008; Sontag et al., 2011; Wong et al., 2014; Wright and Li, 2012, 2013; Ybarra and Mitchell, 2004; Yilmaz, 2011). For example, in the study of Bauman (2010), cybervictimization was the main predictor of cyberbullying behavior. In addition, Wright and Li (2012; 2013) found that being bullied (either offline or online) was longitudinally related to performing cyberbullying behavior six months later.

One possible explanation for this relationship is that performing acts of cyberbullying can serve as a form of revenge (Hinduja and Patchin, 2014; König et al., 2010; Sontag et al., 2011; Ybarra and Mitchell, 2004). Other scholars coined the idea that this relation between victimization and cyberbullying behavior may be explained by the General Strain Theory (Ak et al., 2015; Wright and Li, 2012; Wright and Li, 2013). The General Strain Theory suggests that individuals who experience strain will have increased levels of anger or frustration and some may use deviant behavior as a reaction to these negative emotions (Agnew, 1992). There are three sources of strain: a) failure to achieve positively valued goals, b) removal of positively valued stimuli, and c) experiencing negatively valued stimuli (Angew, 1992). Following this theory, victims of bullying experience strain (i.e., being bullied as a negatively valued stimulus), which instigates anger and/or frustration and could subsequently lead to performing deviant behaviors, such as cyberbullying behavior. Cyberbullying behavior could possibly give these victimized adolescents a feeling of power (Patchin and Hinduja, 2011). In fact, several studies showed that (cyber)victimization induces feelings of anger or frustration, supporting the idea that being bullied is a source of strain (Lonigro et al., 2014; Hay, Meldrum, and Mann, 2010; Ortega, Elipe, Mora-Merchán, Calmaestra, and Vega, 2009; Wallace, Patchin, and May, 2005). As mentioned prior, others have shown that anger is one of the main predictors of cyberbullying behavior (Gradinger et al., 2012; Lonigro et al., 2014; Patchin and Hinduja, 2011). Linking these findings makes it plausible that the relationship between victimization and cyberbullying behavior could be explained by experiencing feelings of anger or frustration. Recently, in addition to our own study (den Hamer et al., 2014), a study investigated this full sequence of victimization, anger, and cyberbullying behavior, and showed that victimization indeed induced levels of anger, which was subsequently related to becoming a cyberbully (Ak et al., 2015).

The General Strain Theory is an important step toward insights into the underlying processes in the relation between being victimized and becoming a perpetrator of cyberbullying oneself. However, we argue that there is another important variable in this chain of events in being bullied, experiencing increased levels of anger and frustration and becoming a cyberbully. That is, we argue in the following that this process will be reinforced by adolescents' media exposure.

THE ROLE OF MEDIA IN CYBERBULLYING BEHAVIOR

Media are omnipresent in adolescent life (Konijn, Veldhuis, Plaisier, Spekman, and den Hamer, 2015), with adolescents between 11 and 14 years old spending more than eleven hours a day using old (e.g., television, magazines) and new (e.g., online games, social networking

sites) media (Rideout, Foehr, and Roberts, 2010; Strasburger and Hogan, 2013). Only one of the available meta-analyses on cyberbullying behavior briefly mentioned the possible influence of media exposure within cyberbullying behavior, and suggests that more research is needed on this topic (Kowalski et al., 2014).

We propose that media exposure plays an important part in the underlying processes of being victimized (online or offline), getting angry or frustrated, and becoming a cyberbully oneself. Previous research indicates that angry adolescents could show an increased attraction to violent media outlets, possibly in the belief to vent their anger (Arnett, 1996; Flammer and Schaffner, 2003; Olson et al., 2007; Olson, Kutner, and Warner, 2008; Plaisier and Konijn, 2013). For example, in Olson et al.'s (2007) study, 45.4% of adolescent boys used violent video games as a way to "get their anger out." For girls, an exact number is not given, but a table shows that this is about 30%. A second possible reason for turning to violent media when feeling angry is the search for attractive role models. An important part of adolescence is finding an independent identity, in which media figures can serve as heroes to look up to (Konijn, Nije Bijvank, and Bushman, 2007). In violent media, adolescents can find numerous role models that show how to deal with anger, mostly by behaving aggressively (Konijn et al., 2007). A victimized adolescent, who has become angry because of this victimization, could possibly turn to media to find out how other people cope with anger and feelings of rejection. This is supported by Plaisier and Konijn's (2013) finding that social rejection led to an increased attraction toward antisocial and risk behavior media content. Antisocial and risk behavior media content portrays antisocial (e.g., stealing, swearing, fighting) and risky (e.g., binge drinking or taking drugs) behaviors. This type of media content also incorporates violent content, classifying violence as antisocial behavior. Given that media portraying antisocial and risk behavior content is highly popular among youth (Brown and Witherspoon, 2002; Strasburger, 2009; Strasburger, Jordan, and Donnerstein, 2010), we found it overly narrow to merely investigate the role of *violent* media in cyberbullying behavior and decided to also include other antisocial and risk behaviors as shown in the media. We hypothesized that adolescents who were victims of bullying would have increased levels of anger and frustration, which subsequently instigates an increased attraction toward media with antisocial and risk behavior content, possibly in order to vent their anger or in search for attractive role models.

Furthermore, we argued that exposure to antisocial and risk behavior content stimulates cyberbullying behavior. Although debated, numerous research exists showing that exposure to media with violent content increases aggressive behavior (e.g., Anderson et al., 2010; Ferguson & Konijn, 2015; Greitemeyer and Mügge, 2014). From a theoretical level, this is explained by theories like the Social Cognitive Theory (Bandura, 2001) and the Downward Spiral Model (Slater, Henry, Swaim, and Anderson, 2003). The Social Cognitive Theory claims that people learn vicariously through media exposure, that they model their own behavior in accordance with the behavior shown in the media, especially since this behavior is often rewarded in entertainment media (Bandura, 2001; Dal Cin, Stoolmiller, and Sargent, 2012; Konijn et al., 2007). The Downward Spiral Model (Slater et al., 2003) follows this line of thought and suggests that exposure to violent media and aggressive behavior reinforce each other. That is, they state that trait aggressive adolescents show a strong preference for violent media content and high exposure to this type of media reinforces their aggressive behavior, which causes these adolescents to end up in a downward spiral of aggression (Slater et al., 2003; Slater, Henry, Swaim, and Cardador, 2004; von Salisch, Vogelgesang, Kristen, and Oppl, 2011). Following

this rationale, it seems plausible that a relationship exists between exposure to media with antisocial and risk behavior content and becoming a perpetrator of cyberbullying behavior.

Support for our notion that media with antisocial and risk behavior content would reinforce cyberbullying behavior can partly be found in the results of previous research, showing that exposure to violent media content relates to (cyber)bullying behavior. For instance, two studies demonstrated that exposure to media with violent content related to offline bullying perpetration (Kuntsche, 2004; Lee and Kim, 2004). Results of a survey among over 4,000 adolescents (mean age of 13) in Switzerland showed that violence on television and in games was related to offline bullying behavior (cyberbullying behavior was not measured in this study; Kuntsche, 2004). This was corroborated by Lee and Kim (2004), who investigated bullying behavior among 560 Korean junior high school students (mean age of 14), and they showed that exposure to media violence (on TV and on the Internet) was related to offline bullying behaviors (cyberbullying behavior was not measured).

Where the above mentioned studies investigated offline or traditional bullying, more recent research demonstrated that an association exists between violent media exposure and cyberbullying perpetration (Calvete et al., 2010; Chang et al., 2015; Dittrick, Beran, Mischna, Hetherington, and Shariff, 2013; Fanti et al., 2012; Lam, Cheng, and Liu, 2013). A cross-sectional study among over 1,400 Spanish adolescents (mean age of 14) showed, among others, that violence on TV was positively related to cyberbullying behavior (Calvete et al., 2010). In addition, in a longitudinal study among over 1,400 Cyprian adolescents (mean age 13), exposure to violent media content (on TV, internet, in movies and games) was related to higher cyberbullying perpetration rates one year later (Fanti et al., 2012). The same was concluded in a study among almost 400 Canadian parents and their 500 children (mean age of the children was 13), in which both parents and children reported the child's attraction to violent video games (Dittrick et al., 2013). Kids that were highly attracted to violent video games were more likely to perform offline and online bullying behavior. This coincides with the results of a study among almost 1,300 adolescents (mean age of 15) from China, which demonstrated that exposure to violent video games was associated with both being a perpetrator and a victim of cyberbullying behavior (Lam et al., 2013). And finally, in a recent study, 2,315 students (mean age of 15) from Taiwan were surveyed in a longitudinal design (one year in between waves), and results showed that exposure to media violence (on TV, in newspapers, on the Internet and in online games) predicted later cyberbullying behavior (Chang et al., 2015).

This enumeration of research that examined the link between media exposure and (cyber)bullying behavior showed that most studies solely focused on one or two media outlets (e.g., Chang et al., 2015; Fanti et al., 2012) and only investigated the impact of *violent* media content on cyberbullying behavior. As argued above, we expected that it is important to not only examine the role of violent media content in cyberbullying behavior, but to broaden the scope toward media content portraying antisocial and risk behaviors. To do so, we developed an instrument to measure exposure to media with antisocial and risk behavior content, the Content-based Media Exposure Scale (C-ME; den Hamer, Konijn, Plaisier, Keijer, Krabbendam, and Bushman, Under Review-B). This scale measured the extent to which adolescents are exposed to *specific behavior* as portrayed in the media, instead of asking for generic exposure to media fare in general (e.g., hours of playing games, watching television) without taking the specific content into account. The C-ME is thereby independent of the medium: the specific behaviors portrayed can be watched on TV, or through the Internet, games, movies, etcetera. In the introduction of the scale, adolescents are informed that it does

not matter through which media outlet they have seen certain behavior, rather they need to focus on the frequency with which they watched each of the listed behaviors. Sample items from the C-ME are: “How often do you watch (on the Internet/TV/games/mobile phone/DVD) people who shoot at another person?” and “How often do you watch (on the Internet/TV/games/mobile phone/DVD) people who steal?” Adolescents rate how often they are exposed to behaviors, such as fighting, relational aggression, drug abuse, and general antisocial behaviors (e.g., stealing, destroying someone else’s property). The items on the C-ME were based on the extant literature regarding adolescent antisocial and risk behaviors (e.g., Hopf, Huber, and Weiss, 2008) and have been extensively pretested and validated in a number of independent studies (den Hamer et al., under review-b).

In sum, we integrated the relevant factors that appear to explain the relation between being victimized and becoming a cyberbully oneself into a theoretical model, named the Cyclic Process Model. This model specifically includes media use among youngsters, for which a content-based media exposure scale has been developed and validated. The Cyclic Process Model will be further elaborated in the next section.

THE CYCLIC PROCESS MODEL OF CYBERBULLYING BEHAVIOR

The Cyclic Process Model aims to disentangle the underlying processes between being bullied (either online or offline) and becoming a cyberbully. Based on the extant literature discussed above, we hypothesized that two processes would play a role in this relation: a) feelings of anger or frustration following victimization, and b) exposure to media with antisocial and risk behavior content. The Cyclic Process Model (visualized in Figure 1) proposes that a victimized adolescent will get angry or frustrated, and will then try to vent these negative feelings by turning to media with antisocial and risk behavior content, which will stimulate or lower the threshold to bully others in cyberspace. Hence, these adolescents get caught up in a cyclic loop because cyberbullying behavior often results in being bullied again (Walrave and Heirman, 2011; Wright and Li, 2012; Wright and Li, 2013). One study actually showed that cyberbullying others was the main predictor of being cyberbullied oneself (Livingstone, Haddon, Görzig, and Ólafsson, 2011). Since cyberbullying behavior peaks during adolescence and media with antisocial and risk behavior content is highly popular among adolescents, we tested the Cyclic Process Model among this age group. Furthermore, given that most research in cyberbullying behavior is descriptive in nature, and uses cross-sectional data, there is an urgent need for longitudinal research that could shed light onto the causal chains in cyberbullying behavior. Therefore, we first tested the Cyclic Process Model in a cross-sectional setting and subsequently in a longitudinal design.

Figure 1. The Cyclic Process Model.

Testing the Cyclic Process Model in a cross-sectional design revealed that all hypothesized pathways were supported by the data (den Hamer et al., 2014). Note that the last step of the Cyclic Process Model (i.e., cyberbullies become victims again) was not tested due to the cross-sectional nature of the study (i.e., a measured variable cannot be used twice in a cross-sectional path model). While these results were encouraging, a cross-sectional design cannot assess whether the Cyclic Process Model would hold over a longer time span. Therefore, another study was conducted utilizing a longitudinal design.

Longitudinal data for the same variables as in our previous study were collected in three waves throughout one school year in a sample of 1,005 participants, aged 11-17 years. Analyses through Structural Equation Modeling provided a good fit of the empirical data to the theoretical model (e.g., $RMSEA = .01$ (.00-.04), $CFI = .99$; see den Hamer et al., under review-a). That is, the results provided evidence for the Cyclic Process Model to occur *over time*. In fact, the results showed that the relationship between victimization and cyberbullying behavior was completely mediated, both by feelings of anger *and* exposure to media with antisocial and risk behavior content. Also, the feedback loop from cyberbullying at the final stage back to victimization found support in the empirical data. The Cyclic Process Model explained 14.0% of the cyberbullying behavior in the last wave. Together, the cross-sectional and longitudinal studies showed that the Cyclic Process Model holds both at certain time points (i.e., within waves) and over a longer period of time (i.e., over time). The results of testing the Cyclic Process Model showed that victimization is followed by anger and frustration, which instigates using media portraying antisocial and risk behavior. In turn, the sequence may stimulate to perform cyberbullying behavior oneself. These findings add to our understanding of the underlying processes of being victimized and becoming a cyberbully oneself: both victimization-based anger and exposure to media with antisocial and risk behavior content showed to be crucial factors.

As a next step, further analyses on the longitudinal data were performed to increase insights in the role of media use in cyberbullying behavior. Following the rationale of the Social Cognitive Theory (Bandura, 2001), the Downward Spiral Model (Slater et al., 2003), and along with the results of our previous studies, we propose that adolescents' exposure to media with antisocial and risk behavior content would serve as an amplifier of cyberbullying behavior. The results showed that exposure to media with antisocial and risk behavior content was related to higher *initial* rates of cyberbullying behavior. That is, adolescents who more intensely used media with antisocial content also had higher levels of cyberbullying rates at the first wave compared to those lower in such media use (den Hamer and Konijn, 2015). Importantly, results further underscored that exposure to media with antisocial and risk behavior content reinforced cyberbullying behavior *over time*, such that an increase in exposure to media with antisocial content goes hand in hand with an increase in cyberbullying behavior over time during the course of an academic year (details in den Hamer and Konijn, 2015).

Furthermore, we examined whether the effect of media exposure on cyberbullying behavior differed between boys and girls (den Hamer and Konijn, 2015). As described earlier, research on gender differences in cyberbullying behavior showed mixed results. However, in general, boys tend to be more attracted to media with antisocial and risk behavior content (Konijn et al., 2007; Möller, Krahé, Busching, and Krause, 2012). Hence, it might be that cyberbullying behavior increases more strongly over time for boys than for girls. The results showed that the effects hold for both boys and girls in predicting an increase in cyberbullying rates as a function of exposure to media with antisocial and risk behavior content. For boys,

this increase was significant for each subsequent wave, while for girls only from wave 1 to wave 2 the increase in cyberbullying was a clear and significant function of their media use. For them, the increase from wave 2 to wave 3 was less clear and seemed to stabilize (den Hamer and Konijn, 2015). Thus, for both boys and girls, exposure to media with antisocial and risk behavior content reinforced cyberbullying behavior in the long run, most clearly for boys while for girls this effect flattens out after a couple of months.

LIMITATIONS AND FUTURE RESEARCH

Some limitations of the present research may be addressed in future research. First, cyberbullying behavior is changing rapidly (think of the abundant rise of new formats of social media in which cyberbullying could occur), and it is difficult to find a measure that captures all variations of cyberbullying behavior. When we started our research, we chose to use the Cyberbullying Questionnaire of Calvete et al. (CBQ; 2010), which was then among the best cyberbullying behavior measures (e.g., because the CBQ measures various forms of cyberbullying). We are aware that ever since, new types of cyberbullying have emerged (for example, shaming someone on Twitter), but we decided to stick with the CBQ for reasons of consistency in our studies and comparability with many others. Thus, it is possible that the cyberbullying scores in our research are underestimations and that we did not capture all types of cyberbullying. However, even under these circumstances, we found a good model fit and significant relations between cyberbullying behavior and victimization, anger, and especially, exposure to media with antisocial and risk behavior content. Likewise, we found an increase in cyberbullying behavior over time as a function of media use.

Second, the use of the Content-based Media Exposure Scale (C-ME; den Hamer et al., under review-b) may be seen by some as a limitation, because it is a newly developed scale. However, we argue that it is important to measure the impact of the *content* of exposure to media rather than just the frequency of watching television or playing video games, for example, regardless of specific content or solely to violent media content. The C-ME includes a broader spectrum of antisocial portrayals in the media and has currently been tested among 2500 adolescents in different samples and shows to have good psychometric qualities. In fact, the antisocial and risk behavior factor of the C-ME is more strongly related to aggressiveness than a traditional media exposure instrument that solely measured *violent* media content (den Hamer et al., under review-b).

CONCLUSION AND DISCUSSION

The current chapter aimed to illustrate the role of media exposure in cyberbullying behavior as an important step in the Cyclic Process Model (Figure 1). The Cyclic Process Model explains how victimized adolescents could turn into cyberbullies and identifies the processes underlying this relation. The validity of the Cyclic Process Model has been tested in several studies with about 2,000 adolescents. We applied both cross-sectional and longitudinal research designs and found clear empirical support for the Cyclic Process Model. As expected, the relation between victimization (either online or offline) and becoming a cyberbully was mediated by

experiencing feelings of anger or frustration and by exposure to media with antisocial and risk behavior content. Our findings not only explain the mechanisms in the relationship between being bullied and becoming a cyberbully, but also emphasize the reinforcing role of exposure to media with antisocial and risk behavior content. In further investigating the latter, exposure to media with antisocial and risk behavior content predicted both higher starting values of cyberbullying behavior, and a stronger increase in cyberbullying behavior *over time*, for both boys and girls, but more clearly for boys.

Our results are in line with and add to related research. Empirical evidence for the mediating role of anger between being bullied and becoming a cyberbully is now also found in another study independent of ours (Ak et al., 2015). Furthermore, the relation between media exposure and cyberbullying behavior was found in a more narrow sense, that is, to violent media exposure alone (Calvete et al., 2010; Chang et al., 2015; Dittrick et al., 2013; Fanti et al., 2012; Lam et al., 2013). We broadened the scope of media exposure to also include other types of antisocial and risk behavior content, since such content is highly popular among adolescents (Brown and Witherspoon, 2002; Strasburger, 2009; Strasburger et al., 2010). Moreover, we developed a more systematic measurement instrument to assess specific content-based media exposure, independent of media channel, rather than just the frequency of exposure to a particular media outlet (e.g., solely movie violence; den Hamer et al., under review-b). In so doing, our results are based on a more reliable and valid measure of content-based media exposure than in previous media-based studies.

Implications that arise from the empirical support for the Cyclic Process Model, and the reinforcing impact of exposure to media with antisocial and risk behavior content on cyberbullying behavior are manifold. Currently, in cyberbullying research, a shift can be detected from merely descriptive and predictive research onto increasing our understanding and investigating ways to combat cyberbullying behavior, for example with intervention studies (e.g., Cross, Monks, Campbell, Spears, and Slee, 2011; Hinduja and Patchin, 2014; Jacobs, Völlink, Dehue, and Lechner, 2014; van den Broeck, Poels, Vandebosch, and Van Royen, 2014). Our findings suggest that such intervention studies should pay close attention to adolescents' media exposure, and in particular adolescents' exposure to media with antisocial and risk behavior content. Also, future research should consider how adolescents cope with anger and frustration, since the Cyclic Process Model shows that these emotions mediate the relation between being victimized and becoming a cyberbully. Some studies have shown that individuals who used media with antisocial content to cope with their anger were even more aggressive after this media exposure (Bushman, 2002; Bushman, Baumeister, and Phillips, 2001). More adaptive coping styles for anger could possibly help break the cycle among victimization, anger, media use, and cyberbullying.

Moreover, future research is warranted to examine whether the Cyclic Process Model works differently for adolescents with different personality characteristics. For example, low empathy is a predictor of cyberbullying behavior (Ang and Goh, 2010; Steffgen et al., 2011). Perhaps, the Cyclic Process Model works differently for adolescents who are low versus high in empathy. That is, it could be hypothesized that victimized adolescents who are high in empathy do not become angry when victimized. Or, when they do become angry following victimization, perhaps high empathic adolescents use other means to cope with it and do not turn to media with antisocial and risk behavior content.

Another personality trait that warrants further attention in relation to the Cyclic Process Model is internalization vs externalization of negative emotions (e.g., Kim, Conger, Elder, and

Lorenz, 2003). Adolescents who internalize the victimization-induced anger and frustration may not feel the need to be exposed to antisocial media content, while the adolescents who externalize their anger may be more attracted to this media content. And perhaps the externalizing adolescents react differently to this media use than the internalizing adolescents.

In conclusion, our research found clear evidence for the Cyclic Process Model, which expands our understanding about the underlying mechanisms in the relation between being bullied and becoming a cyberbully oneself. The Cyclic Process Model shows how victimized adolescents get caught up in a cyclic process of being bullied and bullying others. These victimized adolescents experience negative emotions (i.e., anger or frustration) and by seeking relief in media with antisocial and risk behavior content, they become cyberbullies themselves. This does not solve anything, since cyberbullies often become victims again.

Furthermore, the Cyclic Process Model underpins the important impact of exposure to media with antisocial and risk behavior content. While possibly trying to vent their anger, the adolescents become eventually aggressive, resulting in performing cyberbullying behavior themselves. The Cyclic Process Model is the first to integrate media exposure in a theoretical model, providing insight into the underlying processes of cyberbullying and how it evolves over time. Many questions remain about adolescents' reasons for becoming a cyberbully, but the Cyclic Process Model brings us one step further in our understanding of the mechanisms underlying cyberbullying behavior.

Chapter 14

CYBERBULLYING: THE NEED TO EXTEND THE CONCEPT BEYOND PEER AGGRESSION

Jacek Pyżalski*, PhD

Adam Mickiewicz University, Poznań, Poland

TRADITIONAL SCHOOL BULLYING

School bullying research began in the 1970s in Norway. The scientific interest in this issue was the result of the adverse effects associated with victimization, including suicidal ideation, suicidal attempts, and depression. These mental health consequences, psychosomatic complaints, and learning difficulties are associated with victimization by school bullying (Hymel & Swearer, 2015; Klomeck et al., 2009; Monks et al., 2009; Olweus, 1993).

Studies have been mostly conducted on examining the aggressive acts constituting bullying in the school context. Young people who were involved as bullies, victims, and bully-victims belonged to the same group based on the formal structure of school (e.g., a class) or other institution (e.g., sport team). This has been reflected by measurement instruments, specifically definition or behavior based questionnaires or peer nominations. In both cases, respondents were young people who took part in the study revealing peer aggression experiences within the group in which they belonged.

This finding reveals broader social group dynamics, suggesting that research should take into account the impact of bystanders (Salmivalli, Voeten, & Poskiparta, 2011).

Olweus (1993) defined three features that should be present at the same time to constitute certain hostile acts as bullying. Those include: repetition – aggressive acts are not one-time experiences (e.g., a quarrel concerning a specific situation) but a series of negative experiences which are performed for a longer period, imbalance of power – perpetrators are much stronger than a victim due to physical power, great numbers of them, or psychological power (e.g., a perpetrator has better communicational skills compared to a victim), and intention – the acts are planned as harmful by perpetrators.

* Corresponding Author's Email: pyzalski@amu.edu.pl.

Aggression acts conducted by perpetrators may have various characteristics, according to the behaviors undertaken by them. Traditionally, they include: physical bullying when perpetrators use physical force against victims or their belongings, verbal bullying including vulgar or unpleasant language against victims, and relational bullying which often involves excluding a victim from peer relations and activities. These definitions have been widely accepted and used as a basis of school bullying studies and practical intervention programs (Smith, 2010; Smith, 2014).

It is crucial to understand that the bullying definition is closely related to its consequences. Bullying is widely defined as more harmful than other peer aggression acts due to the presence of the three characteristics described above. This means that there are greater negative mental health outcomes for those involved in bullying, especially when the behavior includes the three features of bullying. This has been empirically proved using both cross-sectional and longitudinal studies (Hymel & Swearer, 2015, Smith, 2014). However, it is worth noting that some researchers argue that peer aggression which does not include the three bullying features may also be seriously harmful for victims. Stemming from this, they suggest that researchers should have a broader scope on peer aggression not restricting it to cases of bullying (Finkelhor, Turner, & Hamby, 2012).

FROM SCHOOL BULLYING TO CYBERBULLYING

Similarly to the interest in school bullying that started in Norway after a series of tragic suicides by young peer aggression victims, the interest in bullying conducted via ICT also started after a few serious cases widely described by the media. This brought attention to the situations where ICTs and the Internet might be used as tools to conduct aggression among young people. The two well-known examples were the Star Wars Kid case and the Megan Meier case. In both cases, both perpetrators and victims were young people that knew each other from school. The cases led to serious consequences, including mental health problems in the first case and the tragic suicidal death in the latter.

These outcomes gained the publics' and researchers' attention on the features that made cyberbullying potentially qualitatively different from traditional school bullying. Cyber perpetrators have a greater opportunity to easily forward hostile messages to a wider public (e.g., on social networking sites), such messages could have been sent to others multiple times, prolonging the cyberbullying experience.

It is also easier for perpetrators to remain anonymous, making it much harder for a victim to defend herself or himself. Cases like these include behaviors that represent traditional bullying characteristics. On the other hand, they suggested that some new characteristics are present in cyberbullying (Nocentini et al., 2010; Tokunaga, 2010). Based on the cyber aggression research conducted previously, it is reasonable to focus on these behaviors using traditional bullying characteristics in the cyberbullying context. In Table 1, comparison of the mechanisms behind the three bullying characteristics are described within the context of cyberbullying behaviors. In some cases of cyberbullying, the mechanisms are the same in both contexts, particularly in situations when bullying and cyberbullying overlap (e.g., students from the same class). Hostile acts occur many times both online and offline (i.e., repetition), the power dynamics are the same in the face-to-face and online contexts (i.e., imbalance of power),

and the rationale behind the negative actions is to cause harm (i.e., intention). As research shows that the overlap of bullying and cyberbullying is common, we do not know whether the same individuals are involved. For example, Pyżalski (2012) found that almost 46% of youths who were traditional perpetrators were also cyberbullies. Additionally, one traditional victim in five was also a cybervictim. In cases when bullying and cyberbullying were perpetrated together by the same perpetrator(s), both phenomena seemed to be just the same set of actions at least from a victim's perspective. In many cases, such acts are, contrary to popular beliefs, not anonymous (Bottino et al., 2015; Hinduja & Patchin, 2009; Kowalski & Limber, 2007; Kowalski, Limber, & Agatson, 2008). As shown in the table, in some cases, new mechanisms connected to specific features of the online content and computer mediated communication occur in cyberbullying. Another important consideration is that they are all present in only some cases of cyberbullying. For example, repetition caused by durability of the material published on the internet is only present in situations when such contents are published. In many cases, such a situation is not present since many cyberbullying acts take place in one-to-one communication between a victim and a perpetrator. Someone may send an unpleasant e-mail or short message to another person (Dooley, Pyżalski, & Cross, 2009; Pyżalski, 2012). This can be said also about intention. In many cases of cyberbullying, perpetrators claim that their intention was different and that they did not intend to harm someone else. In particular, 37% of Polish adolescents indicated that they sent a message to someone on the Internet or via mobile phone that was intended to be a joke but caused serious harm to the recipient. The fact that the act has not been intentionally planned does not mean that subjectively it is not attributed as intentionally harmful by a victim (Pyżalski, 2012). There is empirical data suggesting that a new understanding of traditional bullying features in the cyber context is needed. For example, many studies show that cyberattacks including the publication of materials are perceived as the most harmful by victims (Pyżalski, 2012; boyd, 2007). This illustrates a new understanding of repetition. Cyber contexts may also change the dynamics of power. For example, – one in eleven victims of traditional bullying were a cyberperpetrator, often in retaliation for hostile acts he or she experienced in school (Pyżalski, 2012).

BEYOND PEER AGGRESSION

There is a lot of empirical data that supports the usage of the cyberbullying construct as the natural subsequent construct stemming from traditional school bullying. There are two main reasons for this. The first is that adolescents widely use computer mediated communication to extend their offline peer relationships, mostly those from school contexts.

That means that most of the group dynamics both positive and negative show consistency between the online and offline environments (Subrahmanyam & Greenfield, 2008; Reich, Subrahmanyam, & Espinoza, 2012). The second is that most of the studies reveal overlap between bullying and cyberbullying roles. It is often the same students who engage in and experience peer aggression in both contexts (Pyżalski, 2012). However, there are arguments to leave out the peer context of cyberbullying since young people on the Internet have “the opportunity to interact with a variety of people, in a potentially less personal way” (Reich, Subrahmanyam, & Espinoza, 2012, p. 374).

Table 1. Traditional bullying characteristics in bullying and cyberbullying

	Mechanisms in traditional (face to face bullying)	Mechanisms in cyberbullying
Repetition	Caused by perpetrators repeating their hostile actions many times over a longer period	The mechanism can be the same as in traditional bullying. However, it may also involve a situation when a perpetrator's carries at an act only once (e.g., publishes photos of a victim on the internet) and the repetitive victimization is caused by durability and multiplication of the content by people other than a perpetrator.
Imbalance of power	Caused by physical or psychological power (e.g., a perpetrator has better communicational skills in comparison to a victim)	The mechanism can be the same – particularly in situation when cyberbullying is an extension of traditional face-to-face bullying within the same social group (e.g., school class). However, it may also be caused by better technological skills of those perpetrating. Additionally, imbalance of power may be caused by anonymity of aggressive acts, especially when victims do not know who publishes materials against them.
Intention	Stems from a perpetrator's willingness to harm another person	Cyberbullying may be intentional similar to traditional bullying. However, some serious harmful acts may be conducted without negative intentions due to computer mediated communication features that may facilitate unintentional harmful actions.

That means that the Internet by its nature allows young people to communicate with a broader scope of people from close friends to total strangers. This opens new possibilities as well as new threats.

Young people may conduct hostile acts and suffer online attacks from people other than their peers. It is worth noting that although some scientists researching cyberbullying analyze it as a peer phenomenon the instruments they use do not reflect this behavior as a peer-related issue. For instance, Bottino et al. (2015) analyzed ten studies researching cyberbullying.

In all cases, the questions used the survey instruments included victimization and perpetration subscales, but that the items were phrased as “someone,” or “another person.” This method allows participants to answer in a very broad sense including all cases when they have been attacked via the Internet by a peer or someone else. This is probably one of the reasons why numerous studies on cyberbullying present extremely high rates of cyberbullying perpetration reaching about 75% in some studies (Juvonen & Gross, 2009; Katzer, Fetchenhauer, & Belschak, 2009, Kowalski et al., 2014).

The need for extending cyberbullying out of the peer context is also justified by the fact that some cyberbullying cases can “spill over” into the school context or other contexts, bringing additional consequences.

In a meta-analysis, Bottino et al. (2005, p. 466) found that victims' emotional distress is higher when the following types of cyberbullying are present: "episodes in which the aggressor was an adult; publication of a picture of the child or adolescent; and episodes accompanied by aggressive contacts off-line, like receiving a telephone call or when the aggressor went to the victim's house." The identity of the perpetrator is an important consideration. Whittaker and Kowalski (2015) tested a typology proposed by Pyżalski, (2011; 2012) by focusing on the relationship between victims and perpetrators.

The findings revealed that cyber aggressive comments directed toward random people known only online occurred most frequent and perceived as the most acceptable. Cyber aggressive comments directed toward peers were seen as the least acceptable and the most malicious and offensive, and the most likely to be labelled cyberbullying.

Therefore, it is important that cyberbullying should be examined by taking into account who is using ICT in a hostile way and who is receiving the abuse as well as the relationships between the individuals.

WHEN A VICTIM IS NOT A PEER

When I started my research on using an online instrument to measure cyber-attacks, I decided not to ask specific quantitative questions but instead use a qualitative grounded theory approach (Pyżalski, 2012). That meant I asked my respondents both students and teachers general questions in interviews and focus groups about whether they used the internet or mobile phones to do something unpleasant to others. I also conducted unstructured observations of such behaviors by young people on the Internet in order to record their natural activities. This could be treated as a kind of triangulation that led to construction of electronic aggression perpetration typologies by young people (and also adults). Peer aggression based on the offline group where a victim and a perpetrator(s) belong is only one of the types identified.

Electronic peer aggression (cyberbullying). Many students taking part in the interviews and focus groups indicated that their peers were targets of unpleasant aggressive actions. Peers were in many cases those they knew in offline contexts – mostly students from the same class. The negative interactions were often connected to hostile actions happening in offline contexts, e.g., someone have been called names at school and via cell phone messages simultaneously. In many cases, the cases described seemed to not be very serious and they did not fulfill traditional bullying definition. For example, the presence of imbalance of power had not been involved in many of the cases since the students were friends who have been quarrelling at times but not consecutively. In other cases, students experienced something that they described as minor incidents with peers, indicating that the victim was not harmed. These results may partially help to understand results from other studies showing that almost four in ten Polish adolescents believing that electronic peer aggression was more harmful than traditional bullying (Pyżalski, 2012). Not all peer electronic aggression and traditional aggression were taken seriously.

As to the "new" features present in cyberbullying, it is worth noting that peer aggression is often not anonymous. In many cases, perpetrators utilize social networking site, which is a relatively open environment, or operate mobile phones, with phone numbers displayed.

Each of these examples make it pretty clear who the perpetrator is. Such findings are aligned with many quantitative projects showing that only some acts of electronic aggression possess anonymity feature (Hinduja & Patchin, 2009; Kowalski & Limber, 2007; Kowalski, Limber, & Agatson, 2008).

Anonymity seems to be a feature of cyberbullying or peer electronic aggression. Many times researchers treat anonymity of cyberbullying as a new phenomenon brought by new communication technologies. This is clearly not true since some forms of physical aggression, particularly those concerning damaging belongings of a victim, and covert relational bullying can be carried out anonymously as well.

Although it is always taken for granted that anonymity makes electronic peer aggression worse, this may be not that obvious. The respondents indicated that anonymous acts, particularly when rare do not bring any serious distress – they are often interpreted as rude behavior of someone who is not brave enough to communicate openly. Contrary, when perpetrators are known and belong to the same peer group, the acts are perceived as more harmful. More serious electronic peer aggression acts rarely occur. Many of them were the acts typical to electronic communication that have not been available before in traditional contexts.

For instance, one adolescent girl has been discussed a peer's family problems on her social networking site. This made the situation more harmful by revealing the sensitive information to potential viewers. The harm might have been worse due to the long lasting character of Internet content and what is called by boyd (2008) as invisible audience, providing the imbalance of power present in traditional bullying but brought by technology features and the ways the technology is socially used.

Another example is a kind of electronic aggression that is called impersonation (Kowalski, Limber, & Agatson, 2008). For example, a boy oversaw a peer's password for Facebook profile, and then he logged into the peer's account and sent unpleasant comments to other users who thought that the boy was the actual account owner.

In many cases, perpetrators conducting hostile electronic actions did not indicate any negative intentions. They indicated that they engaged in the acts as a joke or hoax.

Young respondents taking part in the study also indicated different levels of relationships with victims, such as a former or current romantic partner, close friend, or young people they knew from school or where they lived. A situation involving a former romantic partner resulted in more mental health consequences as described by victims.

In summary, not all electronic aggression is cyberbullying. The context always decides what makes it cyberbullying.

Electronic Aggression against Teachers

Young people experience hostile relationships with their teachers and this is not unique to the digital era. Teachers and other educational staff also experience electronic aggression. During the interviews, some respondents, usually teachers, described situations when a teacher or other school staff members have been attacked on the Internet. For example, the school headmaster presented a case when one student had sent a series of letters insulting teachers to their school e-mail addresses. Additionally, revealed situations when students were sending unpleasant messages via text messages.

Electronic Aggression against the Vulnerable

Some students admitted being involved in online aggression against people in unfortunate situations, such as being homeless and alcohol addicted. This kind of aggression usually involved short films published on portals, such as YouTube. The involvement of young perpetrators may have two different forms. They can be producers of the aggressive materials, although perpetration of this form of aggression is rare.

Most often young people were active viewers, positively commenting, rating hostile videos positively, or praising the producers of the materials. Analyzing this kind of aggression as media aggression makes this phenomenon a serious issue, due to the psychosocial and moral consequences for both perpetrators, bystanders, and victims. The form of aggression includes an imbalance of power because sometimes victims in this videos are sometimes not aware of the harm they experience and are helpless.

This makes such acts clearly unethical. Modeling of aggressive behavior in viewers may be occur as they are often around the same age as producers of the harmful content. Additionally the aggressive content is not fictional that took place in the offline world. Viewers often show acceptance by providing positive comments and high ratings, which may give the impression that those kinds of materials are socially accepted.

Aggression Against Random Victims (Random Electronic Aggression)

A lot of respondents indicated that they have attacked people electronically that they have no relationship with. Such acts were usually spontaneous situations influenced by a comment or a behavior of the victim that perpetrators did not like, such as during a forum or chat conversation.

Sometimes the reactions described by the respondents were very emotional and openly aggressive toward victims. It is worth indicating that such behavior is generally targeted against victims that are completely unknown to an aggressor. Those who admitted perpetrating these behaviors sometimes indicated the potential low-risk of potential legal actions taken by a victim in order to identify and punish them.

Electronic Aggression Against Groups (Bias Cyberbullying)

Sometimes students admitted attacking whole groups. For example, they published comments insulting all fans of a certain singer or sport team.

Those comments were often published in places where a lot of potential Internet users could see them, e.g., Facebook wall or as a comment on a public access forum. Although this kind of electronic aggression is not personalized, each person affiliating themselves with a certain insulted group might suffer. This is vital as affiliation to groups, particularly peer groups, is an important developmental stage of adolescence.

Electronic Aggression Against Celebrities

Another target of young perpetrators was widely known individuals, such as actors and singers. Electronic attacks of this kinds were almost never conducted directly through one-to-one communication.

Most often respondents were writing abusive comments about celebrities on gossip portals where short scandalized messages concerning famous people are published. Sometimes such comments, texts, or rarely visual materials were presented on perpetrators' blogs or their profiles on social networking sites.

CONCLUSION

The presented analysis of literature and research showed that the cyberbullying concept should be extended. The complexity and diversity of acts involved suggest that the simple concept of cyberbullying may be too simplistic to describe this phenomenon. I suggest adoption of a wider concept such as electronic aggression. This umbrella term covers a wide range of hostile cases where ICTs are used to harm others. The distinction here is connected to the instruments and environments where the aggression takes place. Those acts could be divided and the typologies may be based on at least two aspects. The first formal feature relates to how the aggression is conducted. This could be based on traditional bullying characteristics (i.e., repetition, imbalance of power, intention) or "new" features, such as anonymity or the publication of digital content. The next aspect concerns the relationship between a perpetrator(s) and a victim(s). It is not how the aggression is conducted that is important but the identity of actors involved. The issue is whether victims and perpetrators are connected based on a group membership. Young people's relationships may be based on formal groups (e.g., a class, a sport team) or informal groups (e.g., peer group in the neighborhood). These groups may also occur online in some way. In such groups, attacking a victim or victims by people from the peer group might heighten the severity of victimization. These findings are corroborated by Whittaker and Kowalski's (2014) study. They found that my typology showed that this kind of electronic aggression is perceived as relatively more damaging than other forms. Victims may be different kinds of people that are strangers to victims (e.g., unknown Internet users, groups, celebrities). Analysis of these different contexts suggests that both the mechanisms and consequences of different kinds of electronic aggression may vary. This means that the measurement should reflect contextual factors in a way that the results should differentiate different kinds of electronic aggression. This might also influence intervention that should consider these contextual aspects of electronic aggression based on relationships between victims and perpetrators.

The elaboration of typologies is still in its preliminary stage. The research presented thus far refers only to adolescents as perpetrators of electronic aggression. However, these typologies might be extrapolated to other groups as well. Generally speaking, the new typologies might influence the way measurement tools are constructed that could yield more accurate and valid cyberbullying research.

Chapter 15

DOES CULTURE MATTER? CYBERBULLYING PERPETRATION AND CYBERVICTIMIZATION IN THE MEDITERRANEAN SEA REGION

Fatih Bayraktar*, PhD

Eastern Mediterranean University, Famagusta, North Cyprus

INTRODUCTION

The Mediterranean Sea is the biggest inland sea in the world. According to the population density, the population is highest in this region, especially along the coastlines. Recent statistics on internet penetration rates indicated that 9% of worldwide internet use derives from 16 countries which have coastlines on the Mediterranean Sea. This relatively high rate of Internet use may bring both opportunities and risks to individuals. The main aim of this chapter is to review the research on one online risks (i.e., cyberbullying perpetration and cybervictimization) in the Mediterranean Sea Region.

Cyberbullying is defined as an “aggressive, hostile, or harmful act that is perpetrated by a bully through an unspecified type of electronic device” (Tokunaga, 2010, p. 270). Cyberbullying is often described as the online continuum of traditional bullying (Gradinger, Strohmeier, & Spiel, 2009; Hinduja & Patchin, 2008; Machačková, Dedkova, Sevcikova & Cerna, 2013; Olweus, 2012; Riebel, Jager, & Fischer, 2009; Wade & Beran, 2011), or as a specific form of indirect bullying that involves the use of electronic devices to carry out bullying (Hemphill et al., 2012; Li, Smith, & Cross, 2012). On the other hand, in the case of cyberbullying, a degree of technological expertise is required; cyber-bullies are much more invisible or anonymous compared to traditional bullies, and the act of bullying in cyberspace typically happens when the bully and victim are physically distant (Cowie, 2009; Li et al., 2012). A comprehensive review, which included databases (i.e., Science Direct, PsychInfo, Medline, Scopus, Ebscohost), revealed that national and international studies focusing on cyberbullying in the Mediterranean Sea Region were generally from Italy, Spain, Turkey,

* Corresponding Author's Email: fatih.bayraktar@emu.edu.tr.

Greece and Cyprus. Although it is difficult to say that all of these five countries share similar characteristics associated with Mediterranean culture, it can be suggested that they are mainly countries with collectivistic cultural tendencies, except Italy which is characterized as an individualistic country (Green, Deschamps, & Paez, 2005; MacDonald, 2010; Suh et al., 1998). Therefore the following parts of the chapter focused on cyberbullying perpetration and cybervictimization research in Cyprus, Greece, Italy, Spain, and Turkey, respectively. After reviewing the literature, similarities or differences in the variables predicting cyberbullying perpetration and cybervictimization in these countries will be discussed and the question “Does culture matter?” will be revisited.

RESEARCH IN CYPRUS

Research on cyberbullying is relatively new in both Northern and Southern Cyprus. This is mainly because of a lack of knowledge about the issue in both communities and the lack of attention in academic settings. Therefore, there is little research focused on cyberbullying perpetration and cybervictimization in Cyprus.

Özçınar and Aldağ (2012) recruited 800 students from five universities in North Cyprus. It was found that both cyberbullying perpetration and cybervictimization was associated with the death of a parent. Gender comparisons indicated that males were more involved in both cyberbullying perpetration and cybervictimization. The results also showed that the risk of cyberbullying perpetration and cybervictimization increased with the use of computers and the Internet. In another study conducted in North Cyprus, Tabak and Köymen (2014) examined sending and receiving unkind messages as indicators of cyberbullying perpetration and cybervictimization, respectively. The sample included 40 English preparatory school students of the European University of Lefke. They found that 40% of the students received unkind messages while 50% of the students reported that they sent unkind messages to someone. Using college students from three universities in North Cyprus, Bayraktar, Dedkova and Machackova (2014) tested the associations among independent self-construal, femininity-masculinity, cyberbullying perpetration, cybervictimization. A total of 393 participants (56.2% females, 44.8% males) between the ages of 19 and 35 ($M = 24.25$, $SD = 2.51$) participated in the study. The results revealed that higher independent self-construal orientation mediated and moderated the association between femininity and cybervictimization. More specifically, independent self-construal served a protective function against cybervictimization for feminine participants.

Some research has also focused on cyberbullying perpetration and cybervictimization in South Cyprus. Although, the Republic of Cyprus is recognized as the only legal entity in Cyprus, two communities (Greek Cypriots and Turkish Cypriots) have lived separately in the North and South parts of Cyprus since 1974. Because of different life contexts and educational/administrative systems in both communities, they are considered separate. Fanti, Demetriou, and Veronica (2012) examined a series of protective (i.e., perceived social support from family, peers, and school) and risk factors (i.e., being involved in school bullying perpetration and victimization, being exposed to media violence, callous-unemotional traits, impulsivity, and narcissism) related to cyberbullying perpetration and cybervictimization using a two wave longitudinal design. A total of 1,416 adolescents were recruited from schools in South Cyprus. Their findings indicated that there was longitudinal continuity between school

bullying and cyberbullying. Callous-unemotional traits at Time 1 were related with cyberbullying at Time 2 with a time gap of 1 year. Also, exposure to media violence was found to be a risk factor for both cyberbullying perpetration and cybervictimization. Also focusing on adolescents from South Cyprus, Floros et al. (2013) recruited 2,684 high school students in order to examine the role of parenting and personal factors in cyberbullying involvement. They found that affectionless parental control (i.e., high maternal and paternal overprotection with low maternal and paternal care) was associated with adolescents' involvement in cyberbullying. The findings also showed that cyberbullies had emotional difficulties, conduct problems (i.e., hyperactivity), interpersonal problems with peers, and antisocial tendencies.

RESEARCH IN GREECE

Empirical research on cyberbullying in Greece began in 2005 (Antoniadou, & Kokinnos, 2015). Increases in Information and Communication Technologies (ICT) penetration and utilization are suggested as contributing to the "cyberbullying epidemic" in Greece (Tsaliki, 2010). Additionally, some researchers have suggested that the ongoing economic crisis could have an impact on cyberbullying rates because rapid economic changes are known to be related to increased violence among young people (Kalliotis, 2000). One of the first studies on cyberbullyingin perpetration and cybervictimization in Greece dates back to 2008, and it was conducted by Kapatzia and Sygkollitou. A total of 544 high school students (ages 16-19) from the area of Thessaloniki were recruited. Self-reported cyberbullying perpetration and cybervictimization rates were 15.2% and 20.5%, respectively. Comparisons on gender indicated that boys were more involved in cyberbullying via cell phones, while girls used the Internet more for cyberbullying. Gountsidou (2008) conducted a study on behalf of the Committee of Social Policy of the Aristotle University of Thessaloniki. The participants were 194 freshmen University students.

The results revealed that cyberbullying involvement rates were low in this sample: 6% for cybervictimization and 1% for cyberbullying perpetration. It was also found that cyberbullying was common in chat rooms, social network sites, and instant messaging services. Two independent studies were conducted on cybervictimization by the Adolescent Health Unit of the University of Athens in 2007 and 2008 with 900 and 315 adolescents (Tripodaki et al., 2008). The results indicated that cybervictimization rates were 4.2% in the larger sample and 5.8% in the smaller sample. Utilizing data collected from the European Action Safe Net Home project, Sygkollitou and colleagues (2010) found that 54% of the 450 students in this sample were cybervictimized. A follow-up study was conducted in 2009 and 2011 with 1,221 adolescents (age range: 15-18 years old; Fisoun, 2011). The results showed that cybervictimization rates increased from 14.5% to 28.3% in two years.

Taken together, these studies reveal different prevalence rates. Antoniadou, and Kokinnos (2015) discussed a factors which might have contributed to these differences. Some factors include a lack of a common definition of cyberbullying, different tools used to measure the issue, and the use of empirically untested self-reported questionnaires. For these reasons, researchers have directed their attention to predictors of cyberbullying involvement.

In one study, Lazuras and Ourda (2012) recruited 125 secondary school students from Athens, and they examined the predictive roles of empathy, attitudes, social norms, risk

prototypes, and self-efficacy beliefs for traditional (face-to-face) bullying and cyberbullying in youths' cyberbullying perpetration. The results revealed that not only did affective empathy negatively predict cyberbullying but self-efficacy beliefs fully mediated the relationship between empathy and cyberbullying.

Other research has focused on personality factors in predicting cyberbullying involvement. In this research, Kokkinos, Antoniadou, Dalara, Koufogazou, and Papatziki (2013) examined the associations among cyberbullying involvement, big five personality traits, and coping strategies among 300 preadolescents. The findings indicated that cyberbullying involvement was predicted by low agreeableness, low conscientiousness, and high neuroticism. Cyberbullying involvement was also related the maladaptive coping strategies of aggression, resignation, and passive avoidance.

Kokkinos and Antoniadou published two independent studies in 2013 (Kokkinos, & Antoniadou, 2013a; Kokkinos, & Antoniadou, 2013b). The first study included 429 students (age range: 10-18 years old) and found that cyberbullying (similar to traditional bullying) was predicted by lack of cooperation and sensation seeking traits (Kokkinos, & Antoniadou, 2013a). The second study included 430 University students (Kokkinos, & Antoniadou, 2013b). The results revealed that cyber-bully/victimization was predicted by anxiety, depression, hostility and interpersonal sensitivity symptoms and on all psychopathic traits, whereas boredom susceptibility, depression, grandiosity, callousness–unemotionality and insecure attachment predicted cyberbullying. Cybervictimization was significantly predicted by gender, depression, grandiosity and callousness–unemotionality.

Some research has focused on gender differences in cyberbullying involvement among Greek youths. In particular, Floros, Siomos, Fisoun, Dafouli, and Geroukalis (2013) recruited 2,017 adolescents whose ages were between 12 and 19. They found that girls were significantly more likely to have been cyberbullied than boys. In addition, both cyberbullying and cybervictimization was predicted by maternal and paternal overprotection, impulsivity, loneliness, depression, and social discomfort. In another study investigating parenting and cyberbullying involvement, Makri-Botsari and Karagianni (2014) examined the associations between parenting styles and cyberbullying involvement among 396 secondary school students. The results showed that authoritative parenting style was negatively related to cyberbullying perpetration, while authoritarian parenting was positively related to these behaviors. There was no significant correlation between authoritative or authoritarian parenting styles and cybervictimization.

RESEARCH IN ITALY

Research on cyberbullying in Italy began in 2008. Pisano and Saturno (2008) found that 14% of middle-school students and 16% of high school students were cyberbullied. They found no gender differences in cyberbullying involvement among the middle-school sample, but females experienced more cybervictimization in the high-school sample. Focusing on mobile phone and Internet bullying, Guarini, Brighi, and Genta (2009) found that middle and high school students used mobile phones more to cyberbully others.

Similarly, Mura, Bonsignore, and Diamantini (2010) also found that 10% of students in their sample of 475 middle and high school students in Milan, Italy reported that they were

cyberbullied. Mobile phones and the Internet were two main tools used to cyberbully others. Focusing on behaviors which represent cyberbullying, Nocentini and colleagues' (2010) findings revealed that Italian adolescents perceived sending unkind text messages and sending a compromising photo as indicators of cyberbullying but not getting access to someone's password and removing someone from an online group. In a cross-national study conducted by Ortega and colleagues (2012), they found that Italian adolescents had the highest rates of cyberbullying involvement through the Internet, compared to adolescents from Spain and England. Furthermore, Italian victims were felt greater anger when compared to their Spanish and English counterparts. They cautioned interpretations of their results as "anger" might be expressed and perceived differently across nations. Similar research was conducted by Schultze-Krumbholz et al. (2015) who utilized latent class analysis to identify classifications of involvement in traditional and cyberbullying across six European countries, including Italy. The results showed that more Italian adolescents were involved in the bully-victim category when compared to adolescents from Poland, Spain, the UK, Germany, and Greece.

Menesini, Nocentini, and Camodeca (2011) evaluated the role of morality and values in traditional bullying and cyberbullying. They recruited 390 adolescents from four high schools in Tuscany, Italy. The results indicated that immoral and disengaged behaviors were associated with both traditional bullying and cyberbullying. Menesini et al. (2011) discussed the key role of morality in both forms of bullying. The authors found that immoral and disengaged behaviors predicted both traditional and cyberbullying. Further investigating predictors of cyberbullying involvement, Brighi, Guarini, Melotti, Galli, and Genta (2012) found that traditional victimization (both direct and indirect) predicted cybervictimization among 2,326 Italian adolescents. Different associations were found for males and females such that low self-esteem in family relationships was a predictor of cybervictimization among males, while feeling lonely in relationships with parents related to cybervictimization among females. Utilizing participants from the same study, Guarini, Passini, Melotti, and Brighi (2012) further investigated the role of gender, age, self-esteem, loneliness, and perceived school climate in relation to traditional bullying and cyberbullying. They found that perceived loneliness in one's relationship with parents, low self-esteem, and conflict with teachers increased the risk of perpetrating both traditional bullying and cyberbullying. Baroncelli and Ciucci (2014) examined the association between trait emotional intelligence and bullying in a sample of 529 Italian preadolescents. The results indicated that the regulation and use of emotions (as indicators of emotional intelligence) were negatively related to both traditional bullying and cyberbullying. Some research has focused on the psychological outcomes associated with cyberbullying involvement. In this research, Brighi and colleagues (2012) investigated the associations among self-esteem, loneliness, and cyberbullying. They found that cybervictimization was related to decreased self-esteem and loneliness.

RESEARCH IN SPAIN

Unlike the earlier research in the other countries, which focus on prevalence rates, one of the first studies published on cyberbullying in Spain focused on the emotional impact of cybervictimization. Ortega, Elipe, Mora-Merchan, Calmaestra, and Vega (2009) recruited

1,671 Spanish adolescents to evaluate the emotional impact of traditional bullying and cyberbullying on victims.

Results indicated that cyberbullying had an impact on victims in two ways. One group of victims reported that they had not been affected by either bullying or cyberbullying. The second group indicated that they suffered from negative emotions as result of their victimization. Following up research investigating prevalence rates of cyberbullying revealed that 29% of adolescents in a sample of 2,001 reported that they were victimized via the Internet, while 24.6% were bullied through mobile phones (Buelga, Cava, & Musitu, 2010).

Girls and juniors in high school were more at risk for cybervictimization. Nocentini and colleagues (2010) conducted research on labels, behaviors, and definitions of cyberbullying in Spain. Spanish adolescents perceived sending unkind text messages and removing someone from an online group as indicators of cyberbullying but not getting access to someone's password or sending a compromising photo.

A cross-national study investigated rates of cyberbullying involvement in England, Italy, and Spain (Ortega et al., 2012). Frequent victimization through the Internet was lowest for adolescents in Spain when compared to adolescents from Italy and England. In addition, Spanish victims reported less anxiety and fear.

Del Rey, Elipe, and Ortega-Ruiz (2012) conducted a short term longitudinal study involving 274 adolescents (age range: 12-18 years old) from two schools in South Spain. The results showed that offline aggression and victimization predicted later cyberbullying perpetration. However, cyberbullying didn't predict later traditional bullying perpetration. Therefore, they concluded that cyberbullying is a continuum of traditional bullying perpetration and a compensation strategy for traditional victimization. In other research, Calvete, Orue, Estevez, Villardon, and Padilla (2010) developed a questionnaire, called the Cyberbullying Questionnaire, to understand cyberbullies' profiles in a sample of 1,431 adolescents. They found that boys perpetrated cyberbullying more often than girls. The results also indicated that cyberbullying was significantly related with the use of proactive aggression, justification of violence, exposure to violence, and perceiving less social support from peers. Other research has focused on comparisons of the predictors associated with traditional bullying and cyberbullying. In particular, Casas, Del Rey, and Ortega-Ruiz (2013) recruited 893 secondary school students from Cordoba, Spain. Their results revealed that traditional bullying and cyberbullying shared similar risk factors (i.e., safety problems in school and negative peer interactions). On the other hand, problematic internet use (which defines excessive and addictive use of internet) uniquely predicted cyberbullying perpetration and the lack of control of personal information online uniquely predicted cybervictimization.

Navarro, Yubero, Larranaga, and Martinez (2012) recruited 1127 primary school students to evaluate the interrelations between cybervictimization, social anxiety and social competence. They concluded that fear of negative evaluation from peers, also interpersonal difficulties and lack of appropriate social skills predicted cybervictimization. Focusing on the associations of cybervictimization to self-esteem and loneliness, Brighi and colleagues (2012) found that cybervictimization was related to decreased self-esteem and loneliness. Utilizing a longitudinal design, Gamez-Guadix, Orue, Smith, and Calvete (2013) investigated the associations of cybervictimization to problematic Internet usage, depression, and substance use among 1,021 adolescents (age range: 13-17). They found that cybervictimization at Time 1 predicted depressive symptoms and problematic internet use at Time 2 with a time gap of 6 months. Moreover, higher depressive symptoms and more substance use at Time 1 predicted

cybervictimization at Time 2. The results revealed that there was a reciprocal relationship between depressive symptoms and cybervictimization.

RESEARCH IN TURKEY

Similar to studies in other Mediterranean countries, except Spain, the first publications focused on the prevalence and nature of cyberbullying. For example, Aricak et al. (2008) examined the prevalence rates of cyberbullying and cybervictimization in a sample of 269 secondary school students. The rates were 35.7% for cyberbullying perpetration, 23.8% cyberbullies-cybervictims, and 5.9% for cybervictimization. Males were more often involved in cyberbullying perpetration and cybervictimization when compared to females. The secondary aim of the study was to investigate the coping strategies of these students. They found that almost 33% of the students used active strategies, such as blocking the aggressor, and 25% asked for help from peers and parents. In another study in the same year, Topçu, Erdur-Baker, and Çapa-Aydın (2008) recruited 183 adolescents from public and private schools. They found that students in public schools reported more cyberbullying perpetration and cybervictimization compared to their peers in private schools.

Accordingly, using internet mediated communication tools more frequently predicted cyberbullying involvement among public school students but not students from private schools. Dilmac (2009) investigated the relationship between psychological needs and cyberbullying among 666 undergraduate students. When the criteria “at least once in the past” was used, 22.5% of the students reported that they cyberbullied others, and 55.3% reported that they had been cybervictimized. Compared to females, males reported more cyberbullying. The results indicated that aggression and the need of attention from other people predicted cyberbullying. On the other hand, cybervictimization was related to the need for affiliation. Other research has focused on the rates of victimization and bullying in both the cyber and face-to-face context.

In such research, Erdur-Baker (2010) recruited 276 adolescents (age range 14-18) to examine the co-occurrence between traditional bullying and cyberbullying. The results indicated that 32% of the participants had been victimized in both forms. The rate of bullying in both social contexts was 26%. Males were more involved in cyberbullying and cybervictimization when compared to the females. Other research by Yilmaz (2011) examined cyberbullying in a sample of 756 middle school students living in Istanbul. The prevalence rates were 17.9% and 6.4% for cybervictimization and cyberbullying perpetration, respectively. Males were more involved in cyberbullying when compared to females. The primary tools for cyberbullying were instant messages and social network sites. For males, massive multiplayer online games were a risk factor for cybervictimization. The results also indicated that most of the students did not know how to cope with cyberbullying effectively. Burnukara and Ucanok (2012) recruited 868 adolescents from different secondary and high schools in Ankara. The main aim of the study was to examine the overlap between traditional and cyberbullying. The results indicated that the rate of co-occurrence was 63%. The prevalence rates for being involved in traditional bullying/victimization/bullying-victimization and cyberforms of these were 31.9% and 21.7% respectively.

Males were more involved in traditional bullying but not gender difference was found for cyberbullying. Arslan, Savaser, Hallett and Balci (2012) examined the prevalence of

cyberbullying and school/home related factors which predict bullying in cyberspace. A total of 372 primary school students were recruited. The prevalence rates were %27, %18 and %15 for cybervictims, cyberbullies and cyberbully-victims respectively. Males cyberbullied more compared to females. Cyberbullying and cybervictimization was negatively related with school satisfaction and academic achievement. Paternal unemployment as a home related factor increased the risk to be a cyberbully three times.

Bayar and Ucanok (2012) examined how students who were involved in traditional bullying and cyberbullying perceived their school's social climate and peer relationships. A total of 1,263 secondary students were recruited for this study. The results revealed that non-involved students perceived their schools and their teachers more positively compared to bullies and bully-victims. Cybervictims perceived their teachers more positively than cyberbullies. Non-involved students, traditional bullies, and cyberbullies had more positive peer relationships than traditional victims and cybervictims. On the other hand, traditional victims and cybervictims perceived their teachers more positively when compared to bullies and bully-victims. Focusing on predictors of cyberbullying involvement, Celik, Atak and Erguzen (2012) investigated the links between personality and cybervictimization among college students from different universities. They found that emotional instability predicted cybervictimization. On the other hand, openness to experience was related negatively to cybervictimization. The results indicated no link between personality traits and cybervictimization. In addition, Eksi (2012) examined the interrelations between narcissistic personality traits, internet addiction, and cyberbullying perpetration among 508 high school students recruited from different schools in Istanbul. Internet addiction mediated the relationship between narcissistic personality trait and cyberbullying. Attention has also been given to the psychosocial adjustment consequences associated with Turkish youths' involvement in cyberbullying. In this research, Cetin, Eroglu, Peker, Akbaba, and Pepsoy (2012) studied the interrelations between relational-interdependent self-construal, depression, anxiety, stress, and cyberbullying involvement in a sample of 258 high school students. Relational-interdependent self-construal was negatively correlated with both cyberbullying perpetration and cybervictimization. The results also indicated that cyberbullying involvement predicted depression, anxiety, and stress. Other research has found this relationship as well but with loneliness and cybervictimization among 389 secondary school students from different schools in Trabzon, a city on the North coast of Turkey (Sahin, 2012). Psychiatric variables have also been found to be associated with cyberbullying involvement. In particular, Ozden and Icellioglu (2014) found that cyberbullying involvement was linked to psychotism among 136 university students.

A BRIEF OVERVIEW OF CYBERBULLYING RESEARCH IN MEDITERRANEAN REGION

The research on cyberbullying in these five Mediterranean countries (i.e., Cyprus, Greece, Italy, Spain, and Turkey) typically began around the same time, parallel to the rest of the world as well. One of the reasons behind this academic interest can be attributed to the rapid increase in Internet and mobile phone use, especially among adolescents and young adults between 2004 and 2008 (Lenhart, Arafeh, Smith, & Macgill, 2008). ICTs created new contexts for bullying, including text messages social network sites, and online games. This review of the research on

cyberbullying in these Mediterranean countries suggests that many of the studies began by focusing on defining the nature of the phenomenon to more current investigations aimed at examining the related risk and protective factors. It is difficult to discuss similarities and differences among these findings because of various sample characteristics and different methods to measure cyberbullying. However, the most stable finding was males' greater tendency for cyberbullying in all countries. Although Tokunaga (2010) stated that both males and females were equally vulnerable in his meta-synthesis, there is a line of research which indicates a constant tendency to cyberbully among males (e.g., Aricak et al., 2008; Li, 2007; Slonje & Smith, 2008).

Another clear result of this regional literature review is that cyberbullying is a growing issue in all five countries. A recent report by Helsper, Kalmus, Hasebrink, Sagvari, and de Haan (2013), which used EU-Kids Online II data, showed a somewhat similar picture of the issue. In this study, a hierarchical cluster analysis was conducted for 25 European countries to find the associations between parental mediation practices and online opportunities, risks, and harm experienced by children and adolescents. The findings indicated that countries which have been outlined in this chapter, except Cyprus, were in the "Protected by Restraint" cluster. This cluster included 10 countries (i.e., Belgium, France, Germany, Greece, Ireland, Italy, Portugal, Spain, Turkey, and the UK). These children and adolescents experienced few online risks and they were protected from these risks by restrictive parental mediation. Cyprus was in the "Semi-Supported Risky Gamers" cluster, which also included Bulgaria, the Czech Republic, Estonia, Poland, and Romania (see Figure 1).

The children and adolescents in this cluster showed higher online risks and their parental mediation was less restrictive. Based on this cluster analysis, it might be suggested that most countries in the Mediterranean Sea region share similar online risks, including cyberbullying perpetration and cybervictimization. However, the role of culture is still ambiguous since neither this report nor cross-national studies discuss this matter. More attention should be given to comparisons that are embedded within cross-cultural theory.

REVISITING THE QUESTION: DOES CULTURE MATTER?

Some researchers stress that culture does not play a critical role in cyberbullying because, similar to traditional bullying, the basis of the problem is universal and linked to human nature (e.g., Görzig & Ólafsson, 2012; Ybarra, Mitchell, & Lenhart, 2010).

On the other hand, a different line of research indicates that the nature (i.e., definition and perception) of cyberbullying can vary according to cultural factors (Calmaestra, Ortega, Maldonado, & Mora-Merchán, 2010; Menesini, 2012). However, in these studies it was not clear how culture explains the variances in cyberbullying.

Also, it is also almost impossible to measure culture as a high-level sociological construct in any empirical way (Gross & Rayner, 1985).

Therefore, lower-level, culture-related psychological constructs which are theoretically associated with cyberbullying can be measured instead of culture itself (Bayraktar et al., 2014).

In this overview of research on cyberbullying in five Mediterranean countries, none of the studies focused on culture or culture-related psychological constructs except one that focused on relational interdependent self-construal (i.e., Cetin et al., 2012). Cross, Bacon, and Morris

(2000) defined relational interdependent self-construal as constructing the self in relation to close interpersonal relationships, but not in relation to a group or society. At this point, it has to be stressed that relational interdependent self-construal was found to be more common in individualistic cultures (Cross et al., 2000; Cross & Madson, 1997a; Cross & Madson, 1997b; Kashima et al., 1995).

Source: Helsper et al., 2013, p. 35.

Figure 1. Country classification based on opportunities, risks and harm, and parental mediation.

Bronfenbrenner's (1979; 2001) ecological theory can be used as a foundation for future studies intended to investigate the role of culture in cyberbullying involvement. Ecological theory explains human development as being nested within systems which are interrelated with each other, including the microsystem, mesosystem, exosystem, macrosystem, and chronosystem. The studies in this review generally focused on microsystem variables (i.e., individual himself/herself, family, peers, teachers) and mesosystem variables (e.g., ICT). Although the macrosystem (in which culture is included) might influence the interactions between all other systems, it was neglected by the studies reviewed in this chapter. Therefore, researchers need to move forward and focus on culture or culture-related psychological constructs as risk and protective factors associated with cyberbullying perpetration and cybervictimization. Though not discussed in many of the chapters in this book, another line of research continues to stress the evolutionary and genetic background of traditional and cyberbullying (e.g., Blumenfeld, 2005; Ouellet-Morin et al., 2013; Volk, Camilleri, Dane, & Marini, 2012).

Therefore, these studies might be unknowingly investigating the "bio" part of Bronfenbrenner's theory, with the general conclusion that bullying (and cyberbullying) are

inevitable because of the genetically and evolutionarily determined power relations among human beings. This conclusion creates a pessimist picture of the phenomenon.

Therefore, it is necessary for research to focus on the flexibility and plasticity of human development from a social-ecological perspective.

Chapter 16

RISKS FACTORS IN CYBERBULLYING: THE MODERATING ROLE OF CULTURE

Natalie Wong*

The Chinese University of Hong Kong, Hong Kong SAR

INTRODUCTION

Due to technology advancements, communicating with the rest of the world can occur within a few clicks. Although the omnipresent Internet has provided us with many conveniences, it has also allowed bullies to reach to their victims almost at anytime and anywhere, which indicates that victims are exposed to potential attacks even when they are alone. As a growing problem among youngsters, cyberbullying has gained increased amounts of attention in recent years. Numerous studies have been conducted around the world in an attempt to identify general predictors and risk factors of this phenomenon.

However, despite the extensive effort to establish meaningful patterns, research results remain highly mixed, and some are even contradictory, such as the relationships among gender, age and cyberbullying behaviors.

In an attempt to explain these discrepancies, recent studies have proposed to use the theory of planned behavior (TPB) as a comprehensive theoretical framework to approach this problem. Cyberbullying perpetration predicted the three major constructs of TPB, including one's subjective norms, attitudes, and perceived behavioral control of their online bullying behaviors (e.g., Ang, Tan, & Mansor, 2010; Burton, Florell, & Wygant, 2013; Heirman & Walrave, 2012; Kowalski, Giumetti, Schroeder, & Lattanner, 2014; Nicol & Fleming, 2010, Williams & Guerra, 2007). Although few of these studies focused on cross-cultural comparisons to examine the moderating role of culture on cyberbullying, systematic differences on risk factors related to the three TPB constructs can be observed when comparing studies from different areas of the world, especially between Western and non-Western cultures.

This distinct pattern implies that culture could have a critical role in moderating cyberbullying perpetration. Therefore, risk factors and consequences of cyberbullying might

* Corresponding Author's Email: nlywong@psy.cuhk.edu.hk

differ across cultures, due to the moderating factor of values and beliefs. The knowledge of culture's role in cyberbullying is necessary for researchers to identify specific risk factors, which could help devise effective interventions for local communities in the future.

Hence, the purpose of the present chapter is to provide a systematic review of the existing cyberbullying research in order to providing a foundation for developing cross-cultural perspective on this phenomenon. Using the theory of planned behavior as the underlying framework, the present chapter will attempt to highlight important cultural differences found in the risk factors associated with cyberbullying. Research implications and future directions will also be discussed.

CYBERBULLYING: A GLOBAL PHENOMENON

Although cross-cultural studies on cyberbullying are rather scarce, there are a number of studies from different parts of the world which show that cyberbullying is indeed a global phenomenon. Cyberbullying has been observed in a number of western countries, such as the United States (e.g., Patchin & Hinduja, 2008), Canada (e.g., Beran & Li, 2006), the United Kingdom (e.g., Smith, Mahdavi, Carvalho, Fisher, Russell & Tippett, 2008), Spain (Calvete, Orue, Estevez, Villardon, & Padilla, 2010), Australia (e.g., Price & Dalgleish, 2010) and Germany (e.g., Riebel, Jaeger & Fischer, 2009).

Figures from recent studies suggest that cyberbullying is a common problem among children, adolescents, and young adults. Kowalski, Giumetti, Schroeder and Lattanner (2014) reported in a recent meta-analysis that the percentage of cyberbullying victimization observed in the past decade ranges from 10% to 40%. On top of the high prevalence rates, a number of recent studies reveal an increasing trend of cyberbullying in some countries (e.g., von Marées & Petermann, 2012).

As a growing problem among youngsters, cyberbullying has gained increased amounts of attention in recent years. Studies conducted around the world have attempted to identify general predictors and personal risk factors for this phenomenon. Although few of these studies have included cross-cultural comparisons to examine the moderating role of culture on cyberbullying, systematic differences on and social risk factors can be observed when comparing studies from different areas of the world, especially between Western and non-Western cultures. The distinct pattern implies that culture could have a critical role in moderating cyberbullying perpetration.

CYBERBULLYING IN ASIA

The world's internet penetration rate has increased sharply in the past decade, due to the invention of smart phones and maturation of the telecommunication network. Although regions which reported the highest internet penetration rates are Europe, North America and Oceania (Miniwatts Marketing Group, 2014), the number of internet users in Asia is also growing.

In fact, according to Internet World Statistics (2014), the internet penetration rates in certain region in Asia are now higher than some countries in the west and the total sum of internet users in Asia takes up almost half of the world's internet population (45.7%).

Following the rise, cyberbullying has also been observed in studies conducted with samples from Asia, such as China (e.g., 刘琳, 2014), Japan (e.g., Udris, 2014), Korea (e.g., Yang,

Stewart, J.M. Kim, S.W. Kim, Shin, Dewey, Maskey & Yoon, 2013), Hong Kong (e.g., Leung & McBride-Chang, 2013; Wong, Chan & Cheng, 2014), Macau (e.g., 陈桂敏, 2013), Singapore (e.g., Kwan & Skoric, 2013) and Taiwan (e.g., Chang, Lee, Chiu, Hsi, Huang & Pan, 2013). Table 1 shows the prevalence estimates and characteristics of studies conducted with samples from Asia, which include both cross-cultural studies and local research on cyberbullying from China, Korea, Japan, Singapore, Hong Kong and Macau. Definitions of cyberbullying and assessment methods used for each study were also summarized in the appendix.

As seen in the table, prevalence rate in cyberbullying found in Asia tend to be at the lower end of the range that was reported in Kowalski and his colleagues' (2014) meta-analysis. However, it is important to note that prevalence rates can be influenced by various methodological issues as suggested by various studies, such as the specificity of instructions (e.g., whether the definition of cyberbullying was provided to the participants), the design of scales (e.g., single/multiple items, time frame of behavioral sampling), and the specificity of the online platform where cyberbullying is assessed (e.g., some studies measure the prevalence rate of cyberbullying in a specific online platform, such as Facebook, mobile phone, massively multiplayer online game). Hence it is important to take the definitions and assessment methods into account when comparing prevalence estimates across different studies. Although the different prevalence rates found across cultures should only be taken as rough estimates of their relative standing in cyberbullying involvement, there are a few cross-cultural studies, which can provide support to the claim that members of eastern culture tend to participate in cyberbullying less than their western counterparts. Despite quantitative, cross-cultural studies between western and eastern cultures being scarce (5 were identified in this chapter), four of them reported a significant difference in the cyberbullying involvement between the two cultures, with people from the western cultures being more involved in cyberbullying. Some studies have also identified interactions between cultural contexts and various personal risk factors in cyberbullying.

An interesting example of such interaction was found in one study on cyberbullying involvement differences in Japan and the US conducted by Barlett and his colleagues (2014). The two countries are distinctive in terms of culture (i.e., independent self-construal is dominant in the US while interdependent self-construal is dominant in Japan) and level of technology advancement (i.e., Japan was more technologically advanced). They found that cyberbullying involvement was linked to technology advances and independent self-construal, with participants from the US being more involved in cyberbullying when compared to those from Japan. This shows that cultural contexts have a strong moderating role in one's cyberbullying involvement.

To capture how cultural perceptions affect cyberbullying involvement, the present chapter will attempt to explain differences found between eastern and western cultures using the Theory of Planned Behavior (TPB). The theory was originally developed by Ajzen to explain what factors contribute to the intention to perform a specific behavior.

The three constructs in TPB, which Ajzen argued to be the main sources of influence on one's intention to perform a behavior, including attitude, subjective norm, and perceived behavioral control. As the theory takes both personal and social factors into account, it is reasonable to argue that it is an appropriate and promising framework to account for cultural

differences in cyberbullying. In the following section, the Theory of Planned Behavior will be introduced in relation to this field of research.

THEORY OF PLANNED BEHAVIOR VS. CYBERBULLYING

Although there are extensive studies on cyberbullying around the world, recent studies have suggest that this field of research is still lack of theoretical focus (e.g., Kowalski, Giumetti, Schroeder, & Lattanner, 2014; Heirman & Walrave, 2012). Because the field lacks a theoretical foundation, research findings on cyberbullying are scattered and lack of cohesion.

This chapter focuses on the theoretical focus of TPB can provide a suitable framework for the research of cyberbullying, especially when accounting for the cultural differences found between eastern and western cultures. The relationships among the three main constructs of TPB and cyberbullying behaviors are illustrated in Figure 1.

As shown in the figure, an individual’s cyberbullying-related attitude, subjective norm, and perceived behavioral control each make unique contributions to one’s behavioral intention to engage in cyberbullying.

A recent attempt to apply TPB to cyberbullying found that their TPB model accounted for around 45% of the variance in adolescents’ behavioral intention to engage in cyberbullying perpetration (Heirman & Walrave, 2012), which is quite impressive considering the large amount of different risk factors identified in past studies.

Cultural differences in cyberbullying might be accounted for by the interaction between the three constructs of TPB and the dominant beliefs of the respective cultures. This interaction can be illustrated using the Ecological Systems Theory.

Adapted from Heirman and Walrave, (2012).

Figure 1. Theory of planned behavior and cyberbullying.

One’s behavioral intention to engage in cyberbullying perpetration can be understood as the result of the interaction across different ecological systems and the individual. It was suggested that the Internet can be considered as a system within the ecological model (i.e., “Techno-subsystem”; Johnson & Puplampu, 2008) or a distinct setting which is closely connected to the offline environment (Spears & Zeederberg, 2012). Either way, cultural ideologies found in the macro-system can affect an individual’s online behaviors by influencing their cyberbullying-related beliefs. In the following section, cross-cultural and Asian studies on

cyberbullying in relation to how cyberbullying-related attitudes, subjective norm, and perceived behavioral control are manifested in different cultures will be reviewed. By drawing support from different studies around the world, I will attempt to illustrate the unique moderating role of culture in cyberbullying in relation to TPB and suggest future directions for cross-cultural research.

CULTURAL DIFFERENCE AND THEORY OF PLANNED BEHAVIOR

Cyberbullying-related attitudes, which include positive impression of the behavior, and normative beliefs and moral beliefs about online bullying, have been identified as one of the strongest predictors of cyberbullying perpetration in a number of studies worldwide (e.g., Heirman & Walrave, 2012; Yang, 2014). The general finding is that the more positive or appropriate an individual thinks cyberbullying is, the more motivated one is to perform the behavior. A number of studies which investigated into the relationship between “justifications of violence” and involvement in cyberbullying found supporting evidence for this argument, i.e., the more an individual justifies violence, the more he or she is inclined to cyberbully others (e.g., Calvete, Orue, Estévez, Villardón, & Padilla, 2010; Williams & Guerra, 2007).

The predictive power of cyberbullying-related attitudes was also specifically tested under the framework of TPB. Using the Attitude towards Cyberbullying Scale, which asked participants to rate on their thoughts about cyberbullying according to how “disadvantageous,” “unpleasant,” “bad,” and “harmful” they thought the behavior was, Heirman and Wlarve (2012) found a positive relationship between adolescents’ attitude toward cyberbullying and their intention to perform respective behaviors. Results also indicated that adolescents’ attitudes were the most important predictor of perpetration among the three TPB constructs, implying that attitudes toward cyberbullying contribute the most to the behavioral intention to engage in cyberbullying perpetration.

Similar findings were replicated in Asia. In a study conducted in South Korea, Park, Na, and Kim (2014) found that normative beliefs about cyber-aggression were significantly related to cyberbullying perpetration. Specifically, the result showed that the more appropriate one thinks a certain cyber-aggressive behavior was, the more likely it was for him or her to perform such behavior. Another study conducted with a Taiwanese sample also found that positive beliefs about cyberbullying significantly predicted cyberbullying perpetration (Yang, 2014). The results also indicated that positive beliefs were the strongest predictors among all variables tested in the study, which included common predictors such as time spent on the internet and knowledge about cyberbullying.

Results from previous studies seem to suggest that the relationship between attitude and cyberbullying is strong and universal across cultures.

However, there is evidence that the strength of the relationship could vary across cultures, implying a possible cultural moderation effect. A recent longitudinal study, which compared the pattern of growth in cyberbullying behaviors between two culturally distinct groups sampled from Japan and the US, found that cultural contexts moderated the relationship between positive attitudes towards cyberbullying and the actual performance of these behaviors (Barlett et al., 2014). Although positive attitudes toward cyberbullying were related to the increase in perpetration for both groups, the effect was found to be more prominent among the US participants. Therefore, positive attitude toward cyberbullying seem to be a better

motivating factor of cyberbullying for participants from the US. Such differences might be a function of cultural ideologies found in the two countries. In particular, the behavioral intention to engage in cyberbullying perpetration among participants from Japan, which is more collectivistic than the US in general, might be less affected by their personal attitudes toward cyberbullying. This might be because members of a collectivistic culture tend to prioritize group goals over personal attitude or feelings in their decision making processes. Hence, the linkage between personal attitude towards cyberbullying and actual perpetration could be weaker among members of a collectivistic culture. Thus far, no other study has specifically investigated how attitudes or normative beliefs about cyberbullying affect perpetration differently in western and eastern cultures. However, there are studies conducted in Asia, which might help us to understand the “individualist-collectivist divide” found in cyberbullying. Huang and Chou (2010) examined bystanders’ viewpoint of cyberbullying among Taiwanese adolescents. When the participants were asked to provide a reason why they were unwilling to report on or interfere with the cyberbullying incidents they witnessed, many argued that it was “none of their business” and that the victims-under-question were not their friends. Some bystanders even went as far as suggesting that cyberbullying “constitute other’s privacy” and as bystanders, they were not supposed to be involved. Huang and Chou also noted that none of the participants suggested that the fear of being retaliated upon or being the next victim were the reasons for not interfering. Taken together, these findings might suggest that Taiwanese adolescents prioritize group norms ahead of their personal well-being when deciding how to react to cyberbullying incidents. Taiwanese culture is highly collectivistic in which children are taught to obey social norms and follow rules. A person’s own will is often given less priority in collectivistic cultures. Other than studies on cyberbullying, cross-cultural research on moral beliefs and cyber-transgression has also found similar patterns in how members of individualistic and collectivistic cultures differ in their attitudes toward cyber-aggression. Jackson, Zhao, Qiu, Kolenic, Fitzgerald, Harold, and Von Eye (2008) observed cultural differences in morality between the real world and the virtual world in samples recruited from China and the US. Main effects of culture on moral values were found. Specifically, results indicated that having a good moral character was more valued among Chinese than US adolescents, which is not surprising as collectivistic cultures such as China, tend to put more emphasis on values that serve the group. Moral character might be more valued in collectivistic cultures since members tend to view themselves as being dependent on one another. Therefore, moral character is important for the greater good of the group. Although no significant difference was found between the two groups in their level of acceptance toward cyber-transgressions in this study, participants from the US participants believed that perpetration would help to advance their personal goals more than their Chinese counterparts. This result fits with the typical behavioral trend found in individualistic cultures.

As suggested in previous studies on cross-cultural comparisons between individualistic and collectivistic culture (e.g., Triandis & Gelfand, 1998), members of individualistic culture tend to stress values that benefit the individual person. As such, social judgment is guided by person goals rather than group goals.

In addition to the difference found in the relationship between positive attitudes concerning cyberbullying and cyberbullying behaviors between the two cultures, the rate of cyberbullying perpetration was significantly lower in the Japanese sample. Such a finding is interesting because Japanese adolescents are usually more technologically advanced than US adolescents, and advanced technology skills is a risk factor for cyberbullying perpetration (e.g., Erdur-

Baker, 2010). Similar results were found in Li's (2007) study, which compared the patterns of cyberbullying involvement between Canada and Chinese adolescents. Among all the potential predictors of cyberbullying included in the study, such as gender, time spent on the computer, involvement in traditional bullying, and country of origin, country was identified as the most significant predictor of cyberbullying involvement. In particular, after controlling for all predictors, Canadian adolescents were 4 times more likely than their Chinese counterparts to be cyberbullies.

Taken together, these studies suggest that there is some support to culture's unique role in predicting cyberbullying behaviors. Differences found in the frequency of cyberbullying perpetration in the cross cultural studies between US and Japan as well as Canada and China could serve as evidence for the important role of culture as a moderator in cyberbullying. More studies need to be conducted to further test cross-cultural differences in cyberbullying involvement.

CULTURE AND SUBJECTIVE NORMS

Cultural contexts seem to have a unique role in moderating the relationship between attitudes and involvement in cyberbullying. Though the directionality of the relationships between attitudes and cyberbullying perpetration seems to be rather universal, the magnitude of such relationships varies across cultures. Different goal orientation (i.e., personal vs. group) found in individualistic and collectivistic cultures could be one possible factor accounting for the cultural differences found in cyberbullying perpetration. Specifically, personal attitudes about cyberbullying might affect an individual from an individualistic culture more than someone from a collectivist culture due to differences in goal orientation. Further investigation is needed to deepen our understanding of how individualistic and collectivistic cultures contribute differently to cyberbullying behaviors.

Subjective Norms

According to Ajzen (1991), subjective norms are defined as the perceived social pressure to perform (or not to perform) a particular behavior. Therefore, the relationship between subjective norms and behavioral intention is twofold in nature. It can motivate or demotivate someone to perform a particular behavior, depending on whether one thinks the people he or she values would support that particular behavior.

More specifically, the more someone thinks that his or her significant others would support certain behaviors, the more someone is inclined to perform that behavior. Subjective norms can also discourage a person from doing something, if the individual believes that his or her friends and partners disapprove of that behavior.

The relationship between subjective norms and behavioral intention has also been replicated in cyberbullying research. Williams and Guerra (2007) found that cyberbullying perpetration among teenagers were related to their perceptions of whether their peers approve or disapprove of cyberbullying. Similarly, a recent TPB study found that subjective norms regarding cyberbullying were significantly related to the engagement in cyberbullying perpetration (Heirman & Walrave, 2012).

The concept of subjective norms could provide valuable explanations to the cultural differences found in cyberbullying. The different patterns of gender involvement in cyberbullying across cultures seems to indicate how prevalent beliefs in the society can affect one's subjective norms and shape the different bullying patterns across cultures.

Gender Schema and Different Subjective Norms about Cyberbullying across Cultures

Gender differences in cyberbullying involvement have been highly researched. This research reveals mixed findings. Whilst some studies have found that boys were more involved to engage in cyberbullying (e.g., Barlett et al., 2014; Li, 2007), some researchers have found no gender difference in cyberbullying involvement (e.g., Beran & Li, 2005).

Furthermore, there are also a number of studies which have found that girls were more involved in cyberbullying (e.g., Blair, 2003; Nelson, 2003).

Although gender differences found in cyberbullying involvement vary highly across studies in the western countries, research conducted with Asian samples seems to yield more unified results. Table 1 displays studies conducted in Asia (e.g., China, Taiwan, Korea and Japan), with overwhelming findings revealing that boys tend to cyberbully and be cyberbullied more than girls (e.g., Wong, Chan & Cheng, 2014; Huang & Chou, 2010; 陈桂敏, 2013). Though some studies have found no gender difference in cyberbullying involvement (e.g., Tzeng & Huan, 2011), none of the studies have found evidence that girls perpetrate more cyberbullying when compared to boys. A potential explanation for the more unified trend among eastern countries might be due to different gender schemas found in the two cultures.

In a cross-cultural cross-sectional study which compared cyberbullying between adolescents from the US and Japan, Lerner (2011) found few gender differences in both cyberbullying involvement in the US sample. In addition, the US sample shared similar levels of involvement as bullies and victims across all age groups and based on gender. The only significant difference was that girls tend to engage in more exclusion behaviors than boys did. A distinctively different pattern was found in the Japanese sample. Gender differences were found in the choice of indirect and direct aggression. In general, boys tended to cyberbully more and engage in a significantly higher amount of direct verbal bullying behaviors than girls do. The differences observed between the two cultures could be explained by the different gender schemas promoted in western and eastern cultures.

Female members of many eastern cultures, such as Japan, China and Korea, are often taught and praised for acting submissive and gentle in public. Girls who are openly aggressive are often severely degraded, or seen as unattractive in some eastern societies, including Japan. As such, female members of eastern societies might hold subjective norms that discourage their performance of bullying behaviors, especially for direct aggressive behaviors. Western cultures, on the other hand, such as the US, generally hold a more egalitarian view. Therefore, girls from western cultures might feel less pressured to conceal their hostile intent. Cross-cultural studies on how general subjective norms affect cyberbullying behavior are very scarce. In fact, there are only a few cross-cultural studies which investigated the relationship between subjective norms and cyberbullying perpetration. Although research in this area is still limited,

the results found in that study are might shed some light on how cultural contexts can moderate the effect of subjective norms on cyberbullying behaviors.

Cultural Orientation Moderates the Predictive Value of Subjective Norms in Cyberbullying

Results of another study which also compared cyberbullying between samples from Japan and the US indicated that cyberbullying reinforcement (i.e., subjective norms about cyberbullying) was positively related to cyberbullying perpetration for both samples (Barlett, Gentile, Anderson, Suzuki, Sakamoto, Yamaoka & Katsura, 2014). Specifically, it was found that the more an individual felt he or she was reinforced to cyberbully others, the more he or she engaged in cyberbullying two months later at time 2. Although the effect was significant for both samples, it was found to be more pronounced among US participants.

This might seem to be a counter-intuitive result at first glance. Since Japan is more collectivistic than the US, it might be argued that the participants from Japan should be more affected by the opinions of their in-group members. There might be two possible explanations to the counter-intuitive finding. One reason might be related to the nature of the scale used in this particular study. The other reason focuses on vertical collectivism in Japan (described later). Although the 12-item cyberbullying reinforcement-scale used in this study encompassed social reinforcement given by family (1 item) and friends (5 items), half of the items in the scale tapped into intrapersonal reward from cyberbullying perpetration (e.g., "I find it rewarding to cyberbully others online if they deserve it," "I get amusement from sending mean text messages or e-mails to others"). The sum of item ratings comprises the final score of cyberbullying reinforcement. Therefore, finding more pronounced effects of cyberbullying reinforcement in the US sample is consistent as half of the scale stressed the advancement of personal goals in cyberbullying, which fits within the individualistic framework. Japanese participants, on the other hand, might be less affected by intrapersonal rewards as members of collectivist culture tend to prioritize group goals over personal goals.

It can also be argued that the effect of in-group approval might not be as strong in promoting cyberbullying perpetration among Japanese participants due to vertical collectivism. Some studies which investigated this concept suggested that collectivism can be classified as more "horizontal" or "vertical," and Japan is one of the collectivistic countries which promotes the latter (e.g., Singelis, Triandis, Bhawuk, & Gelfand, 1995; Triandis & Gelfand, 1998).

Similar to members of horizontal collectivistic societies, such as China, people who hold vertical collectivistic values also see themselves as an integral part of their in-group and are compliant with in-group pressure. However, different from horizontal collectivistic societies, vertical collectivistic societies promote hierarchy among members. In-group members are not treated as equal, with some having higher status than the others (e.g., Singelis, Triandis, Bhawuk, & Gelfand, 1995; Triandis & Gelfand, 1998).

Hence, it could be possible that Japanese might value larger group norms (such as the general societal value to be harmonious) or opinions from higher-status group members more than those of their close friends or family.

To support for this argument can be found based on research concerning the relationship between interdependent self-construal and bullying perpetration, and how these associations differ between participants from the US and Japan (Barlett et al., 2014).

The predictive value of interdependent self-construal developed by Singelis (1994) was examined in this study. The scale measured how much participants identify themselves as being interdependent according to how much they prioritize the welfare of the (smaller) group(s) they belong to over their personal interests.

The results indicated that the interdependent self-construal-scale was negatively correlated with the frequency of cyberbullying behaviors only for the US sample, which suggests that variations in the level of interdependent self-construal only affected actual cyberbullying perpetration among the US participants but not the Japanese participants.

This finding might seem contradictory at first. However, the interdependent self-construal-scale used in this study had items that tapped into the interests of “smaller” groups or “cliques.”

The insignificant relationship between interdependent construal and cyberbullying behaviors found in the Japanese sample might be evidence that members of a vertically collectivistic culture might be relying on other factors (e.g., higher order social norm) instead of the subjective norms of significant others when deciding on whether to engage in cyberbullying.

On the other hand, members of individualistic cultures who identify themselves as highly interdependent might perform less bullying behaviors as their desire to advance personal goals by bullying others might be dampened by their feelings of connections with the people in their cliques.

The directionality of the relationship between subjective norms and bullying behaviors seem to be rather universal across cultures, i.e., the more one thinks that the people he or she values support certain cyberbullying behavior, the more likely the individual will perform that particular behavior. However, due to different gender schemas, specific pattern concerning gender and cyberbullying might vary widely across cultures.

Furthermore, the strength of the relationship between subjective norms and cyberbullying perpetration might be moderated by different cultural orientations (e.g., vertical vs. horizontal and individualistic vs. collectivistic, etc.).

Further investigations are needed to deepen our understanding on how different subjective norms might explain the cultural differences found in cyberbullying involvement in different cultures. Specifically, it is important to further divide the study on cyberbullying reinforcement into intrapersonal and interpersonal dimensions to better capture the interaction between cultural orientations and different aspects of subject norms.

Perceived Behavioral Control

Traditionally, perceived behavioral control (PBC) was studied in terms of how the perceived ease to perform certain bullying behaviors affects one’s behavioral intention to bully others in face-to-face settings (Ajzen, 1991). General findings on PBC indicate that the easier one thinks it is to perform certain bullying behaviors, the more likely he or she will perform those behaviors. Although few studies on cyberbullying have explored the relationship between PBC and actual perpetration with regards to the Theory of Planned Behavior, past studies on computer literacy and anonymity in cyberbullying could shed light on how PBC affects one’s behavioral intention to bully in an online setting.

There might be two aspects of PBC which could affect one’s behavioral intention to bully or cyberbully others. The first aspect focuses on the “mechanical ease” to perform a bullying

behavior. For example, in the traditional setting, an individual might evaluate his or her comparative physiques with the target when considering whether it is easy to bully that person. In the cyber world, as physiques might not matter as much in face-to-face bullying perpetration, one might evaluate the mechanical ease to cyberbully others based on his or her level of computer literacy instead. In fact, computer literacy is consistently related to the frequency of cyberbullying perpetration (e.g., Erdur-Baker, 2010). The other aspect focuses on the “perceived ease to achieve the goals of bullying,” which involves the evaluations of how easy it is to inflict harm on others without the risk of being socially sanctioned. In the cyber world, the higher possibility of being anonymous while bullying others might increase the perceived ease to inflict harm without the risk of being punished socially (Ajzen, 1991).

Not surprisingly, perceived level of anonymity was found to be associated with the frequency of bullying perpetration online. Although some cross-cultural studies have found that adolescents from different cultures might differ in their levels of computer literacy and time spent online (e.g., Barlett, Gentile, Anderson, Suzuki, Sakamoto, Yamaoka & Katsura, 2014), the relationship between these variables and cyberbullying perpetration is rather similar. Specifically, computer literacy, time spent online, and perceived level of anonymity, which are all related to the PBC of cyberbullying, were positively correlated with cyberbullying perpetration in both western and eastern cultures (e.g., Erdur-Baker, 2010; Hinduja, S., & Patchin, 2008; 楊琬琳, 2014). However, it is important to note that the strength of the relationship between PBC and cyberbullying perpetration could be moderated by normative beliefs about cyberbullying (e.g., Park, Na & Kim, 2014; Yang, 2014). PBC seems to moderate behavioral intention to cyberbully similarly in both western and eastern cultures. However, the present chapter proposes that the study of PBC can be expanded to explain cultural differences found in the behaviors of bystanders and victims of cyberbullying. Specifically, PBC can also predict reactions and behaviors of victims and bystanders when experiencing or witnessing cyberbullying.

Perceived Behavioral Control in Victims and Bystanders: Cultural Difference

As PBC is the perception of ease when performing a desired behavior, PBC in victims and bystanders can be defined as how easy they think it is to defend themselves or intervene in a cyberbullying incident. A factor which might take up a significant portion of PBC in cyberbullied-victims and bystanders is the perceived ease of seeking help when experiencing or witnessing cyberbullying. Therefore, perceptions of parental and teachers’ roles in intervening in cyberbullying could constitute a huge part of PBC, especially among children and young adolescents. Cultural differences in the perception of adults’ role in intervening in cyberbullying have been tested using a cross-cultural study conducted by Li (2008). Three variables, namely “Adults stop cyberbullying,” “victim reporting (to teachers or parents),” and “bystander reporting (to teachers or parents),” were included in the analysis of students’ perception of adults’ role in stopping cyberbullying. The first variable refers to how much the participants believed that adults would stop a cyberbullying incident when notified.

The latter variables refer to whether victims and bystanders were willing to tell adults (e.g., teachers or parents) about cyberbullying. Significant cultural differences were found in the perceptions of adults' role in cyberbullying intervention between the two samples.

More Chinese students reported that adults in schools tried to stop cyberbullying when told, implying that more Chinese students believe that adults will help to combat cyberbullying. Chinese cyberbullied-victims and bystanders were also more likely to tell adults about the bullying incidents they experienced or witnessed than their Canadian counterparts. In fact, the percentage of people who would report the incident to adults varies between the two cultures. Whilst 66% of victims and 60% of bystanders from the Chinese sample would tell adults about their cyberbullying experience, only 9% of bullied-victims and 19% of bystanders would do the same among Canadian participants. Chinese adolescents seemed to believe that adults could help them fight cyberbullying more so than the Canadian adolescents did, which could potentially affect PBC in cyberbullied victims and bystanders.

The author suggested that Confucius teaching, which stresses respect for adults and authorities, could be the reason why Chinese adolescents believed in adults' willingness and power to intervene more than Canadian adolescents. The highly interdependent self-construal found in collectivistic cultures might have also promoted trust for other in-group members, such as teachers and parents among Chinese children.

One study focused on different risk factors associated with cyberbullying among Chinese high school students. In this study, Zhou, Tang, Tian, Wei, Zhang, and Morrison (2013) found that 30% of cyberbullied-victims in their sample would choose to talk to their parents or teachers about their experience of cyberbullying, which was a larger amount than cyberbullied-victims from Canada. The higher level of trust in adults among adolescents in Confucius cultures, such as China, might be a protective factor for cyberbullied victims and bystanders as it grants them with more PBC when dealing with cyberbullying.

Cultural differences found in the perception of adults' ability to intervene in cyberbullying might also have potential implications for culturally specific interventions.

CONCLUSION

In this book chapter, a range of cross-cultural studies from around the world were reviewed with the focus on explaining cultural differences in cyberbullying patterns found in eastern and western countries using TPB.

Since TPB incorporate both personal and social risk factors associated with cyberbullying, it could potentially be an effective framework for explaining cultural differences found in cyberbullying.

The present chapter has provided some support concerning the relationship among cyberbullying-related attitudes, subjective norms, PBC, and cyberbullying, and that such relationships could be moderated by different cultural contexts. Heated topics of interests in the field of cyberbullying, such as gender differences, the effect of adult's involvement and in moderating role of individualistic and collectivistic beliefs in cyberbullying were discussed.

I hope I have illustrated that culture has a unique moderating role in cyberbullying. As cross-cultural studies are very scarce, further studies are needed to deepen our understanding of the moderating role of culture.

Table 1. Prevalence estimates and characteristics of studies conducted with samples from Asia

Study	Written in	Sample characteristics			Concept	Prevalence rate (Self-report)*			Gender involvement**	
		Countries	Age / Grade	N		CB (M or %)	CBV (M or %)	CV (M or %)	CB	CV
陈桂敏 (2013)	Chinese	Macau, China	Middle to high school	1086	Cyberbullying and victimization	18% (adopted two or more types of cyberbullying)	/	13% (experienced two or more types of cyberbullying)	<u>Male</u>	<u>Male</u>

Note: *CB = Cyberbullies, CV = Cybervictims, CBV = Cyberbully-victims (i.e., people who are cyberbullies and cyberbullied victims simultaneously); **Gender involvement: the gender which is more involved in cyberbullying or victimization is listed in the table, NS = the gender difference was not significant; ¹4-point Likert scale: 1 (Rare) to 4 (Always); ²Infrequent bullies: reported engaging in cyberbullying acts a couple to a few times in the school term; ³Frequent bullies: reported weekly or more cyberbullying acts; ⁴6-point Likert scale: 1 (Never) to 6 (Everyday/Almost Everyday); m = month, M = male, F = female; ⁵Bullying “via mobile phone text message (SMS)” or “via mobile multimedia messages (MMS)”; ⁶Bullying “in a chat room”; “via emails,” “via computer instant messages (IM),” “on bulletin boards,” “in newsgroups,” or “via blogs”; ⁷Dichotomous variable: ‘1 = yes’ or ‘0 = no’; ⁸Ever = includes participants who have cyberbullied others at least once in their life time; ⁹6 months = include participants who have cyberbullied others at least once in the past 6 months; ¹⁰5-point Likert scale: 1 (Never) to 5 (Always).

Appendix 1. Table of definitions and measurement of scales in each study

			Measure of bullying and victimization		
Study	Countries	Cyberbullying definition*	Scale	Classification criteria**	
陈桂敏 (2013)	Macau, China	Author listed 7 existing definitions for cyberbullying ^a	The response category for each type of bullying behavior was ‘1 = yes’ or ‘0 = no’	Level of cyberbullying perpetration and victimization is calculated based on how many types of cyberbullying incidents the participant is involved in	
张野, 张珊珊, 徐闻文 & 刘琳 (2014)	China	Cyberbullying refers to bullying through the use of information and communication technology (ICT) ^a	<u>5-point Likert scale</u> (1 = never to 5 = always)	[Cyberbully]	Cyberbullying scale: $M \geq 4$
				[Cybervictim]	Cybervictimization scale: $M \geq 4$
				[Cyberbully-victim]	Both CB ^b & CV ^b scales: $M \geq 4$
刘琳 (2014)	China	Cyberbullying is an extension of traditional bullying, which is defined as the intentional harm of others (who cannot easily defend themselves) using ICT. It can be carried out by a group or an individual ^a	<u>5-point Likert scale</u> (1 = never to 5 = always)	[Cyberbully]	Cyberbullying scale: $M \geq 4$
				[Cybervictim]	Cybervictimization scale: $M \geq 4$
				[Cyberbully-victim]	Both CB ^b & CV ^b scales: $M \geq 4$
尤阳 (2013)	China	The intentional harm of others induced by a group or an individual through the use of ICT ^a	<u>5-point Likert scale</u> (1 = never to 5 = always)	Prevalence rate was estimated using the median scores	
Ang & Goh (2010)	Singapore	"Cyberbullying refers to the willful use of the Internet as a technological medium through which harm or discomfort is intentionally and repeatedly inflicted, targeting a specific person or group of persons"	<u>5-point Likert scale</u> (1 = never to 5 few times a week in the current school term)	[Non-bullies]	No engagement in bullying
				[Infrequent bullies]	A couple to a few times
				[Frequent bullies]	Weekly or more
Ang, Huan & Florell (2013)	Singapore & US	"Cyberbullying refers to the deliberate use of the Internet as a technological medium to intentionally and repeatedly threaten, harm, embarrass, or socially exclude a specific person or group of persons"	<u>5-point Likert scale</u> (1 = never to 5 few times a week in the current school term)	[Non-bullies]	No engagement in bullying
				[Infrequent bullies]	A couple to a few times
				[Frequent bullies]	Weekly or more

Appendix 1. (Continued)

Study	Countries	Cyberbullying definition*	Measure of bullying and victimization			
			Scale	Classification criteria**		
Barlett, Gentile, Anderson, Suzuki, Sakamoto, Yamaoka & Katsura (2014)	Japan & US	"Cyberbullying has been defined as '...bullying and harassment of others by means of new electronic technologies...' (Cost, 2012), which extends the definition of traditional bullying (e.g., Olweus, 1999) by adding a technology component. Individuals can send unkind text messages and emails, post secrets about another for public viewing, and even upload embarrassing photos/videos of others all with the intent to harm others."	<u>6-point Likert scale</u> (1 = never to 6 = everyday / almost every day)	Prevalence rate was estimated using the mean scores		
Chang, Chiu, Miao, Chen, Lee, Huang & Pan (2014)	Taiwan	"Cyberbullying is defined as bullying or harassment through the Internet, cell phones, or other electronic devices (e.g., sending insulting messages, posting digitally altered photos, aggressive comments, sharing someone's embarrassing information, or sending messages that include threats of harm through e-mail, instant messaging, in a chat room, on a web site, or sent to a cell phone) (David-Ferdon and Hertz 2007; Kowalski and Limber 2007)..." This study excluded online sexual solicitation from the operationalization of cyberbullying	<u>5-point Likert scale</u> (never, happened a year ago, a few times within a year, a few times a month and a few times a week.)		10th grade survey	11th grade survey
				[No cyberbullying perpetration or victimization]	No involvement in CB or CV	No involvement in CB or CV
				[Emergence of cyberbullying perpetration or victimization]	No involvement in CB or CV	Involvement in CB or CV
				[Cessation of cyberbullying perpetration or victimization]	Involvement in CB or CV	No involvement in CB or CV
				[Persistent cyberbullying perpetration or victimization]	Involvement in CB or CV	Involvement in CB or CV
Chang, Lee, Chiu, Hsi, Huang, & Pan (2013)	Taiwan	"Cyberbullying is defined as bullying or harassment through the Internet, cell phones, or other electronic devices (ie, sending insulting messages, posting digitally altered photos, online fighting, aggressive comments, sharing someone's embarrassing information, or sending messages that include threats of harm through e-mail, instant messaging, in a chat room, on a Website, or sent to a cell phone)"	5-point Likert scale (never, happened a year ago, a few times within a year, a few times a month and a few times a week.)	[Cybervictim-only]	Cyberbullying scale: $M \geq 3$ "a few times within a year"	
				[Cyberbully-only]	Cybervictimization scale: $M \geq 3$ "a few times within a year"	
				[Cyberbully-victim]	Both CB & CV scales: $M \geq 3$ "a few times within a year"	

Study	Countries	Cyberbullying definition*	Measure of bullying and victimization		
			Scale	Classification criteria**	
Holt, Fitzgerald, Bossler, Chee & Ng (2014)	Singapore	"The study defined bullying as any treatment that a person received that was deliberate, intended to hurt, unjustified, repeated, and carried out by a more powerful person or group, in keeping with the larger research literature on this issue"	<u>4-point Likert scale</u> (1= rarely or never to 4 = very often)	Prevalence rate is based on "at least one cyberbullying experience" in the past year	
Huang & Chou (2010)	Taiwan	"The intentional and repeated harm of others through the use of computers, cell phones, and other electronic devices"	<u>5-point Likert scale</u> (once, twice in a month, once a week, and several times a week)	[Non-Cyberbully] or [Non-Cybervictim] or [Non-Bystander]	No relevant cyberbullying experience at all
				[Cyberbully] or [Cybervictim] or [Bystander]	At least one relevant cyberbullying experience
Jang, Song & Kim (2014)	Korea	"Cyberbullying has been defined as "an aggressive act or behavior that is carried out using electronic means by a group or an individual repeatedly and over time against a victim who cannot easily defend him or herself" (Slonje et al., 2013, p. 26)"	The response category for each question was '1 = yes' or '0 = no'	Prevalence rate is based on "at least one cyberbullying experience" in the past year	
Jung, Leventhal, Kim, Park, Lee, S. H., Lee, M., ... & Park (2014)	Korea	"It was explained to the youth that cyberbullying was considered to have occurred when someone was intentionally and repeatedly harmed bullied or teased using electronic devices, including phones and the internet (chat rooms, e-mail, and instant messengers)"	<u>5-point Likert scale</u> (never, once or twice, a few times, many times, or every day)	Prevalence rate is based on "at least one cyberbullying experience"	
Kwan & Skoric (2013)	Singapore	"Bullying which takes place over communication platforms like email, chat rooms, mobile phones and websites is termed cyberbullying (Campbell, 2005)"	<u>6-point Likert scale</u> (1= never to 6 = more than 10 times since the start of the school year)	Prevalence rate was estimated basing on "at least one form of Facebook bullying" in the past year	

Appendix 1. (Continued)

Study	Countries	Cyberbullying definition*	Measure of bullying and victimization	
			Scale	Classification criteria**
Lerner (2011)	Japan & US	"Cyberbullying has been defined by the same three criteria used in identifying traditional bullying – an imbalance of power, intention to hurt, and repetition over time"	<u>5-point Likert scale</u> (lot of the time, often, some of the time, rarely, never)	Prevalence rate was estimated basing on "at least one cyberbullying experience"
Leung & McBride-Chang (2013)	Hong Kong	"Mason (2008) defined it as "an individual or a group willfully using information and communication involving electronic technologies to facilitate deliberate and repeated harassment or threat to another individual or group by sending or posting cruel text and/or graphics using technological means" (p. 323)"	<u>5-point Likert scale</u> (1= never to 5 = everyday)	[Cyberbully or Cybervictim with "at least one cyberbullying experience"] $M > 1$
				[Cyberbully or Cybervictim with "frequent cyberbullying experiences"] $M > 2$
				[Cyberbully or Cybervictim with "very frequent cyberbullying experiences"] $M > 3$
Li (2007)	China & Canada	"Cyberbully is defined as harassing using technology such as email, computer, cell phone, video cameras, etc. Bullying occurs when people say mean and hurtful things or make fun of another person or calls him/her mean and hurtful names, completely ignore or exclude him/her from their group of friends or leaves him/her out of things on purpose, tells lies or spreads false rumors about him/her, sends mean notes and tries to make other students dislike him/her, and other hurtful things"	The response category for each question was '1 = yes' or '0 = no'	Prevalence rate was estimated basing on "at least one cyberbullying experience"
Li (2008)	China & Canada	"Cyberbullying refers to bullying via electronic communication tools such as email, cell phone, Personal Digital Assistant (PDA), instant messaging or the World Wide Web"	<u>3-point Likert scale</u> (1-3 times, 4- 10 times and over 10 times)	Prevalence rate was estimated basing on "at least one cyberbullying experience"

Study	Countries	Cyberbullying definition*	Measure of bullying and victimization	
			Scale	Classification criteria**
Park, Na & Kim (2014)	Korea	"Smith et al. (2008) defines cyberbullying as "an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself"	<u>8-point Likert scale</u> (never, less than every few months, once a month or so, once in 2–3 weeks, 1–2 times a week, 3–5 times a week, about once a day & several times a day)	Prevalence rate was estimated basing on "at least one cyberbullying experience"
Tzeng & Huan (2012)	Taiwan	Cyberbullying is defined as bullying or harassment through the internet, cell phones, email, blogger, Facebook or other electronic devices (e.g. insult, make fun, spread rumors, make private information public, sending sexual pictures) ^a	<u>4-point Likert scale</u> (1 = never to 4 = often)	Prevalence rate was estimated basing on whether the participant had "at least one cyberbullying experience"
Udris (2014)	Japan	"Intentional and repetitive harmful behavior through the use of information and communication technologies"	Cyberbullying experience overall and during the past six months was coded as two separate dichotomous variables: 0 = no experience; 1 = being a cyberbully.	Prevalence rate was estimated basing on "at least one cyberbullying experience"
Wong, Chan & Cheng (2014)	Hong Kong	"Cyberbullying is generally defined as an individual or a group using ICT to deliberately and repeatedly harass or threaten another individual or group by sending or posting cruel texts or images"	<u>4-point Likert scale</u> (1 = never to 4 = five or more times)	Prevalence rate was estimated basing on "at least one cyberbullying experience" within a 30-day period
Yang (2014)	Taiwan	Cyberbullying is defined as behaviors which aims at attacking or hurting others, which includes devaluing, harassing, threatening and making a person feel embarrassed ^a	<u>5-point Likert scale</u> (1 = never to 5 = always)	Prevalence rate was estimated basing on the median scores of the relevant scales

Appendix 1. (Continued)

Study	Countries	Cyberbullying definition*	Measure of bullying and victimization	
			Scale	Classification criteria**
Yang, Stewart, J.M. Kim, S.W. Kim, Shin, Dewey, Maskey & Yoon (2013)	Korea	"Cyberbullying is defined as a type of traditional bullying which was defined as 'a subset of aggressive behavior that is characterized by over time repetition and an imbalance of power'"	<u>4-point Likert scale</u> with higher scores reflecting greater victimization and bullying	Scores at or above the upper quartile indicated involvement of cyber-bullying
Zhou, Tang, Tian, Wei, Zhang & Morrison (2013)	China	"Cyberbullying is an intentional, repeated, and aggressive act or behavior carried out by a group or individual instrumentally employing information and communication technology (ICT)"	<u>5-point Likert scale</u> (1 = never to 5 = always)	Prevalence rate was estimated basing on "at least one cyberbullying experience"

Note: *Definitions of cyberbullying which are directly quoted from papers are listed in quotation marks; ^aindicates that the text was originally written in languages other than English; **Label of each classification is listed in bracket, e.g., [Cyberbully] and [Cybervictim]; ^bCB and CV are abbreviations of Cyberbullying and Cyberbullying victimization.

INTRODUCTION

Involvement in bullying has been shown to result from a complex interplay between individuals and their wider social environment. Many researchers stressed the need to understand the role of factors on different socio-ecological levels, including parents and family, teachers and school environment, institutional and community contexts, as well as factors at the national and cultural levels (Festl & Quandt 2013; Swearer & Doll 2001; Swearer & Espelage 2004). Recognizing that human behavior (e.g., bullying) has multiple causal factors and multiple outcomes, Swearer and Espelage (2004; 2011) used Bronfenbrenner's ecological systems theory (Bronfenbrenner 1977; Bronfenbrenner 1979) as a starting point to create a socio-ecological framework for understanding bullying involvement. The framework conceptualizes bullying behaviors and experiences as a result of a complex and reciprocal interplay between different levels of a socio-ecological system.

Applying the socio-ecological framework of bullying to cyberbullying, this chapter will synthesize findings from the cross-national survey data of the EU Kids Online II project. The goal of this project was to enhance the knowledge base about new media use among European youth, with a specific focus on experiences with online risks, including cyberbullying. During 2010, a survey covering a large array of questions regarding internet access, use, activities, risks (including cyberbullying), parental mediation, coping and vulnerability was conducted. A random stratified sample of approximately 1,000 internet-using youths aged 9–16 and one of

* Corresponding Author's Email: Anke.Goerzig@UWL.ac.uk.

their parents were interviewed in each of twenty-five European countries¹, yielding a total sample size of 25,142 youths (50% girls). Interviews took place in youths' homes, conducted face-to-face but with private questionnaires completed for sensitive questions. For full details of sampling and procedures, see Livingstone, Haddon, Görzig and Ólafsson (2011a) and Görzig (2012).

Considering the large sample size and the application of a standardized methodological approach across Europe, the EU Kids Online survey data represents a robust comparable evidence base in the European context and offers a unique opportunity for understanding the cyberbullying phenomena. Since 2010, a number of scientific outputs, including articles, books, chapters, reports, and presentations have reported findings based on these data and enabled a deeper understanding of the cyberbullying phenomenon. Each output captured specific segments with regards to cyberbullying, including involvement as a victim or bully, coping with cybervictimization, and harm caused by the experience. This chapter will review these outputs and synthesize the findings across individual, social, and cultural levels in line with a socio-ecological framework of bullying. Upon this synthesis, we aim to offer a complex portrait of the risk and protective factors connected with cyberbullying among European youths.

The socio-ecological approach reflected the need to understand (and work with) different factors which are intertwined with bullying processes. Utilizing an ecological system perspective (Bronfenbrenner 1977; Bronfenbrenner, 1979), these factors were linked with differential levels of the socio-ecological environment, enabling an understanding of the interplay of diverse actors and conditions. In order to understand the complexity of bullying processes among youths, the socio-ecological framework of bullying argues that bullying should be investigated by considering factors linked with the levels of the individual, peers, the family, the school, the community, and the culture (Swearer & Espelage 2011). Most research applying this approach to bullying has differentiated between factors linked with levels associated with the individual, the family, peers, and the school, while fewer have taken into account factors associated with the level of the community or investigated factors that are associated with the cultural level (cf. Swearer & Espelage 2011; Swearer et al., 2006).

The socio-ecological approach has been successfully applied to the research of bullying, while the chapters within this volume depict the application of this perspective in the context of cyberbullying research. Complementing previous research, in our work, we will consider factors associated with cyberbullying within three basic types of levels: the individual, social, and cultural levels. The EU Kids Online model attempts to explain adolescents' online risks and opportunities within a specifically adapted socio-ecological framework (see Figure 1). Guided by this model, the EU Kids Online survey captured variables on the level of the individual as well as their parents, peers, and teachers. In addition, the survey data allows linkage with official country level data, enabling the examination of the *cultural level* of the socio-ecological system². With the youth at the center, we will consider specific factors at different levels of the socio-ecological system.

² The authors acknowledge that the term "culture" is not synonymous with characteristics of a country. However, in line with the socio-ecological model of bullying (Swearer et al., 2011), in this chapter variables at the level of a country are used as a proxy for the *cultural level* of the model which is used to reflect the macro-system in the corresponding work by Bronfenbrenner (1979) and will refer to factors associated with a country's culture in the broader sense within the present work.

In the following section, we will provide definitions related to the concept of cyberbullying and describe the assessment of these behaviors within the framework of EU Kids Online. Further, we will map the factors that emerged from the survey to the three types of ecological levels focused on in our synthesis. Due to space limitations, a detailed list of items associated with each of the variables will not be provided. However, the reader is encouraged to refer to Livingstone et al. (2011a) or Livingstone, Haddon, and Görzig (2012) for a detailed list of items and definitions associated with key variables used within the EU Kids Online survey.

Figure 1. Explaining risks and opportunities: The EU Kids Online model. Adapted from Livingstone et al. (2011b) with the authors' permission.

DEFINING CYBERBULLYING

Despite the lack of consensus in the definition of cyberbullying (e.g., Slonje, Smith & Friséen 2013), most researchers employ definitions similar to that of traditional or face-to-face bullying, namely an act of aggression that is intentional, repetitive, and is directed toward an individual of lower power (Olweus 1993), but they extend it to electronic forms of contact, specifically mobile phones or the internet (Perren, Dooley, Shaw & Cross 2010; Smith et al., 2008). Within the EU Kids Online survey adolescents received the following description of bullying behaviors:

“Sometimes children or teenagers say or do hurtful things to someone and this can often be quite a few times on different days over a period of time, for example. This can include: teasing someone in a way this person does not like; hitting, kicking or pushing someone around; leaving someone out of things.”

Adolescents were asked if someone acted in this kind of “hurtful or nasty way” to them or if they acted in a way that might have felt “hurtful or nasty” to someone else in the past 12 months. Those who indicated that they have experienced this kind of behavior will henceforth be referred to as *victim*, those who indicated to have acted in such a way toward someone else are referred to as *bully*, and those who have indicated to be both a victim and a bully we will refer to as *bully/victim*. Furthermore, adolescents were asked to indicate whether this behavior occurred face-to-face (in person), by mobile phone (e.g., texts, calls, video clips), or on the internet (e.g., email, social networking sites). We will refer to incidences that occurred face-to-face as *face-to-face* or *offline bullying*. Following Smith et al.’s (2008) definition of cyberbullying, within EU Kids Online we employ the term *cyberbullying* to refer to the incidence of bullying via mobile phone and/or on the internet, and *online bullying* to refer to bullying on the internet only. However, when discussing the phenomena in general we will be using the term *cyberbullying* to cover both variables assessed by the survey, online and cyberbullying.

Importantly, drawing on theories of risk (Aven & Renn 2009; Breakwell 2007), we differentiate the occurrence of such behavior, which we refer to as the *risk* (defined as the occurrence of an event which is associated with a probability of harm) from *harm* (defined as actual physical or mental damage as reported by the person concerned) that might be experienced as a result of this behavior. This distinction is reflected in the survey by further follow-up questions for those who had indicated to be a victim. The questions assessed: “how upset did you feel about it (if at all),” representing the measure for *intensity of harm* within the survey. Within the present research synthesis, we will be referring to the occurrence of *harm* if any level of the intensity of harm other than “not at all upset” occurred. Furthermore, the survey assessed the *duration of harm* (i.e., “how long did you feel upset for”) and a *harm index*, which was composite of intensity and duration of harm.

INDIVIDUAL LEVEL FACTORS

The individual level factors incorporate all variables that were directly associated with the young person. These consisted of demographic variables, such as age and gender, as well as psychological factors which included self-efficacy³, sensation seeking⁴, ostracism⁵, and psychological difficulties. Psychological difficulties can further be differentiated into emotional problems, peer problems, conduct problems, and hyperactivity (Goodman, Meltzer & Bailey 1998). Furthermore, variables with regards to the young person’s internet use and activities were examined. Among those were the time and the location where the internet is used as well as platforms and devices used for access. Moreover, the young person’s general online activities (e.g., “used the internet for school work”) and risky online activities (e.g., “sent personal information to someone that I have never met face-to-face”) were investigated (Livingstone & Helsper 2007; Livingstone & Helsper 2010). In addition, psychological variables connected to internet use and activities were assessed, such as excessive internet use, and young people’s *online persona*, i.e., whether they found it “easier to be myself” and were

³ Adapted from Schwarzer and Jerusalem (1995)

⁴ Adapted from Stephenson, Hoyle, Palmgreen, and Slater (2003)

⁵ Adapted from Ferris, Brown, Berry, and Lian (2008)

more likely to “talk about different things” and “talk about private things” on the internet than they would offline (Görzig 2011). Variables also included the young person’s digital skills and beliefs about their internet abilities.

Besides the experience of cyberbullying, other risk experiences and behaviors were assessed. These included other online risks, such as sending and receiving sexual messages, seeing sexual images, meeting new online contacts (online and offline), personal data misuse, and seeing negative user-generated content (NUGC). Offline risk activities, such as missing school lessons, getting drunk, having sexual intercourse, getting in trouble at school or with the police were also considered (Currie et al., 2008).

Finally, factors that were linked with the individual’s response to the experience of the risk associated with cyberbullying were taken into account. These included harm from cyberbullying but also various responses of the young person in an attempt to cope with the experience. These coping responses can be differentiated into general psychological and/or behavioral responses (i.e., trying to fix the problem, hoping the problem would go away by itself, feeling a bit guilty about what went wrong, getting the other person to leave one alone, getting back at the other person), seeking support (i.e., talking to a friend, sibling, parent, teacher or another adult), and responses which were specific to the internet (i.e., stop using the internet, deleting any messages from the other person, changing privacy/contact settings, blocking the person, reporting the problem).

SOCIAL LEVEL FACTORS

The social level factors involve variables that relate to the young person’s social background and their social relationships. Their social background is reflected by socio-economic status and has been divided into low, medium, and high status, which was assessed via the household’s main wage earner’s level of education and occupation. Furthermore, the young person’s parents were asked to indicate whether the language used at home is a minority language, whether their child belongs to a discriminated against group, and is considered to have a disability (e.g., physical, mental health, or learning disability). In terms of social relationships, various factors related to the young person’s parents or carers, friends or peers, and teachers were investigated.

With regard to survey responses obtained from parents directly, their general worries concerning their child (e.g., child being bullied or contacted by a stranger on the internet) and their awareness about their child’s experience of cyberbullying or something upsetting online (i.e., harm) have been captured. Parents also reported whether and how frequently they used the internet and about their confidence in using the internet. In addition, the young person reported on parental awareness of their internet activities (i.e., how much they thought their parent(s) knew about what they do on the internet).

Moreover, youths were asked about mediation of their internet use by parents, peers, and teachers. These were differentiated into five main types of mediation: active mediation of internet safety by parents, peers, and teachers (e.g., “suggested ways to behave towards other people online”), active mediation of internet use (e.g., “do shared activities together with you on the internet?”), and restrictive mediation concerning parents and teachers (e.g., allow use of instant messaging), and parental monitoring (e.g., check which websites you visited) as well as

parental technical mediation (e.g., make use of “parental controls or other means of keeping track of the websites you visit”). Lastly, the young person was asked who from his or her social environment provided or who was sought out for support (i.e., who the young person talked to) upon experiencing cybervictimization or after a bothering incident.

CULTURAL LEVEL FACTORS

The cultural level, also referred to as the macro-system, or “cultural blueprint,” comprises abstract influences, such as economic, social, educational, legal or political systems, which can elicit indirect influences upon individuals and other levels of the ecological system they are a part of (Bronfenbrenner 1977). Not much research has examined the influence of the cultural level on bullying. There has been some research investigating the cultural level in terms of an organization’s culture (Espelage, Berry, Merrin & Swearer 2014); however, none to our knowledge has yet examined the role of a country’s culture as was done by EU Kids Online. Within the ecological framework, we review how much (if any) contribution to cyberbullying can be found by factors located at this level and their interplay with factors from other levels. Variables reviewed at this level are the country variables as well as differences among other variables in their association with cyberbullying shown across countries. Furthermore, variables that are aggregated at the country level and census or other publicly available data from cross-national survey research that have been linked with the EU Kids Online data are considered.

PROCEDURE

In order to synthesise the research outputs from the EU Kids Online survey data examining cyberbullying in relation to the factors of the different socio-ecological levels as described above, the following steps were taken. We searched for all relevant outputs written in English, using academic search databases; we also contacted the members of the EU Kids Online network⁶ via their mailing list and asked them to inform us about existing relevant outputs. After compiling a list of outputs to be reviewed (available in January 2015), outputs were coded using non-exclusive categories. The first type of coding indicated whether the output examined the individual, social, or cultural level (all three types could be present) and whether any interaction between variables across levels was assessed. Second, we coded whether specific factors, which have been described above, were present. These codes were divided into nine categories for the individual level (i.e., demographics, internet use and activities, internet skills, other risk experiences and behaviours, offline bullying, associations between victimisation and bullying, general psychological factors, coping responses, and harm), five categories for the social level (i.e., socio-economic status, parental use and activities, parental awareness, mediation by and support seeking from parent, peers or teacher) and four categories for the

⁶ EU Kids Online is a multinational research network. It seeks to enhance knowledge of European children's online opportunities, risks and safety. It uses multiple methods to map children's and parents' experience of the internet, in dialogue with national and European policy stakeholders. It has been funded by the EC's Better Internet for Kids programme.

cultural level (i.e., policy regulations, national statistics, country level aggregates, cultural norms and attitudes). Variables to be associated with each category were agreed upon between coders (both authors) as was the final result of the coding process. After the coding process, findings for each code were reviewed and synthesised with regard to all three levels and all named factors.

RESULTS

Individual Level

The individual level refers to all variables with an immediate link to the young person. Factors considered on this level are possibly those assessed and studied the most in relation to cyberbullying. Given the scope of this section it will be divided into three parts. The first part will refer to the experience of cyberbullying only (the risk) and it examines the links with demographic variables, internet use and activities, other risk experiences, and psychological variables. This will be followed by outlining the responses to cyberbullying victimization, which capture coping responses as well as harm experienced from victimization. Those responses will be linked to similar variables as the risk. Finally, we will outline similar or differential patterns of risk and harm with the investigated variables and (if present) link those further with particular coping responses.

Experiencing Cyberbullying

Overall, 6% of youth who responded to the survey have indicated to be a victim of online bullying while 3% indicated to have bullied others online (Livingstone, Haddon, Görzig & Ólafsson 2011b). In terms of demographic variables, both gender and age have been found to be associated with the risk of being involved in cyberbullying. Generally, girls and older adolescents reported being cyberbullied more often than boys or younger youth (Green & Brady 2013; Lampert & Donoso 2012; Laurinavičius, Žukauskienė, & Ustinavičiūtė 2012; Livingstone et al., 2011b; Vandoninck, D’Haenens & Segers 2012). Furthermore, it was shown that the gender differences that are generally prevalent for offline bullying (more boys) are not found in youth reports of having bullied others online (Görzig 2011; Lampert & Donoso 2012). However, bullying others online or per mobile phone increased slightly with age (Lampert & Donoso 2012; Livingstone et al., 2011b).

The relation of time and frequency of internet use with cyberbullying was demonstrated by various analyses. The odds of being bullied online increased for those youth who used the internet daily as opposed to those who did not (Staksrud, Ólafsson & Livingstone 2013; Stald & Ólafsson 2012). The average time spent online each day also predicted the odds of being bullied online (Laurinavičius et al., 2012; Staksrud et al., 2013). In addition, those who exclusively bullied others offline (i.e., face-to-face) as opposed to those who bullied others online and/or by mobile phone spent less time online each day (Görzig & Ólafsson, 2013; Görzig 2011). Not many analyses have been carried out on the physical location of internet use and cyberbullying. One study found that being bullied online was associated with internet use at home in the child’s own bedroom (Stald & Ólafsson 2012), while another showed that private

access to the internet failed to differentiate between cyberbullies and face-to-face bullies (Görzig & Ólafsson 2013).

In terms of internet platforms used, it appears that social networking sites (SNS) and instant messaging (IM) play a prominent role in cyberbullying incidences. When comparing platforms it emerges that youths are mostly bullied on social networking sites (SNS) and by instant messaging (IM), and the least by gaming sites or chatrooms (Livingstone et al., 2011b). It was further shown that about half of those bullied online encountered this on SNS and by IM. Moreover, youths with a SNS profile were twice as likely to be bullied online independent of age, gender, time spent online, and daily use of the internet (Staksrud et al., 2013). In addition, those youths who were involved in online bullying (whether as bully or victim) were more likely to have a social networking profile than those involved in offline bullying only (Görzig 2011). Furthermore, having an SNS profile did increase the likelihood of being a cyberbully as opposed to an offline only bully, particularly among girls (Görzig & Ólafsson 2013). Lastly, being bullied via SNS or IM has been found to be related to mobile technology use; adolescents who had been victims of cyberbullying and used a mobile device to go online were more likely to have been bullied via social networking sites (SNS) and instant messages (IM) than those who did not use mobile devices (Görzig & Frumkin 2013).

In terms of activities, cyber and online bullies could be differentiated from offline bullies by generally engaging in more risky online activities but not by their engagement in risky offline activities. With regards to psychological variables connected to internet use and activities it was found that cyber and online bullies when compared to face-to-face bullies showed higher beliefs about their internet abilities and found it easier to be themselves online as well as found it easier to talk about different and more private things online than they would offline (Görzig & Ólafsson 2013; Görzig 2011). Finally, there was a small but significant association of excessive internet use with bullying others online (Smahel & Blinka 2012).

The experience of online or cyberbullying has been linked with the experience of other online risks. In general, associations of small effect sizes were found with other online risk factors (Galács & Ságvári 2012). Furthermore, youth who were bullied on the internet were found to have experienced misuse of personal data more often than those who have not been bullied (Kupiainen, Suoninen & Nikunen 2012). A study investigating the relation between the role of involvement in cyberbullying (cyberbully, cybervictim or cyberbully/victim) and two aspects of NUGC (i.e., viewing of web-content related to self-harm and to suicide) showed that compared to those not involved in cyberbullying, viewing web-content containing suicide was higher for cybervictims and cyberbully/victims but not for cyberbullies. Viewing of web-content with self-harm was higher for all cyberbullying roles but especially for cyberbully/victims. Furthermore, none of the relationships between cyberbullying role and viewing of suicide-related web-content was shown to be mediated by psychological problems (Görzig 2014). In addition to the association with other online risks, cyberbullying has also been found to be linked with offline risks. A confirmatory factor analysis showed that all online and offline risk experiences of 11-16 year olds in the EU Kids Online sample loaded significantly on a shared general risk factor (Görzig & Livingstone 2014).

Another offline risk experience not included in the group of offline risks as defined by EU Kids Online but with a particular conceptual importance to the experience of cyberbullying is offline or face-to-face bullying. Fifty-six percent of online bullies said they had bullied others face-to-face and 55% of online victims also reported to be victims of face-to-face bullying (Hasebrink, Görzig, Haddon, Kalmus & Livingstone 2011).

Additionally, it was found that among other predictors being bullied offline was the strongest predictor of online bullying as being bullied offline increased the odds of being bullied online 10 fold (Laurinavičius et al., 2012). Moreover, upon investigating various links between the experience of offline risks, offline bullying, and offline victimization with cyberbullying and cyberbullying victimization, the largest associations existed between offline bullying and cyberbullying and between offline victimization and cyberbullying victimization. However, additional associations were found between cyberbullying and cyberbullying victimization (Vazsonyi, Machackova, Sevcikova, Smahel & Cerna 2012).

The latter finding alludes to another link between risk experiences, that is, the link between the experience of cyberbullying as a perpetrator with the experience of cyberbullying as a victim. It has been shown that bullying and being bullied tend to go together (Görzig 2011; Hasebrink et al., 2011; Lampert & Donoso 2012). In general, across online and offline bullying experiences, around 60% of those who bully have been bullied by others (either online or offline). However, of those who have bullied others offline only 10% were bullied online while of those who have bullied others online (only) 18% have been bullied offline. Hence, bullying and being bullied by others mostly occurs through similar modes - either online or offline. Among those who do not bully others, being bullied is relatively rare – 8% offline only, and 4% online (Görzig 2011; Hasebrink et al., 2011). Furthermore, regression analyses controlling for socio-demographic variables and psychological variables showed that being a cyberbully was the strongest predictor for being a cybervictim and being a cybervictim was the strongest predictor for being a cyberbully (Lampert & Donoso 2012).

The experience of cyberbullying has been found to be associated with various psychological factors. Generally, both online or cyberbullying victimization as well as perpetration showed a positive relationship with psychological difficulties, self-efficacy, and sensation seeking (Lampert & Donoso 2012; Laurinavičius et al., 2012). In addition, studies have examined the relationship between the different roles of cyber- or online bullying (i.e., being a bully, a victim or both – a bully/victim) with the various psychological variables compared to those who were not involved. Those who were cybervictims but not bullies showed higher sensation seeking, ostracism and psychological difficulties (i.e., full scale and the subscales conduct, emotional and peer problems). Those who were cyberbullies but not victims also showed higher sensation seeking and psychological difficulties (i.e., full scale and the subscales conduct and emotional problems) but not ostracism. Finally, those who were cyberbully/victims showed higher sensation seeking, ostracism and psychological difficulties (i.e., full scale and the subscales conduct and emotional problems). In addition, online bully/victims showed higher psychological difficulties (full scale) than those who were online bullies but not victims. Moreover, online bullies or bully/victims were higher in sensation seeking than online victims and online victims showed higher ostracism than online bullies (Görzig 2011 2014; Hasebrink et al., 2011). Finally, being cyberbullied via a mobile as opposed to a stationary device, i.e., being cyberbullied on-the-go, was associated with higher sensation seeking and psychological difficulties (Görzig & Frumkin 2013).

Responding to Cyberbullying

There are a number of ways that young people react to or cope with cyberbullying victimization. Overall, young people choose several of these strategies, including general psychological and/or behavioral responses, seeking support (i.e., talking to someone), and responses which are specific to the internet.

Talking to someone was the most popular strategy used by 77% of victims bullied online. In terms of responses specific to the internet, youths most often blocked the person (46%) and deleted hurtful messages (41%). More scarcely, youth stopped using the internet (20%) or changed settings (18%). The least employed strategy was to report the problem (9%). With regards to more general psychological and/or behavioral responses, the most common strategy was trying to fix the problem (36%), 24% of the victims hoped the problem would go away by itself, and 12% felt a bit guilty about what went wrong. Regarding the efficiency of the coping strategies, blocking the sender was evaluated as the most helpful strategy by 78% of victims who were bothered by the victimization, 69% found that stopping to use the internet was helpful, and 58% deleted the message. Most victims (81%) also used a combination of strategies (D'Haenens, Vandoninck & Donoso 2013; Livingstone et al., 2011b; Vandoninck, d'Haenens & Roe 2013).

Several studies have focused on other individual factors that are connected with the choice of specific coping strategies. It has been shown that girls were more likely to talk to someone about the experience than boys. Girls were also more prone to try to fix the problem, yet they more often hoped that the problem would go away and less often reported it than boys (Cerna, Machackova & Dedkova, in press; D'Haenens et al., 2013; Livingstone, Görzig, & Ólafsson, 2011; Vandoninck et al., 2012; Vandoninck et al., 2013). Younger victims less often blocked the sender, changed the settings, or tried to fix the problem and more often stopped using the internet. Nevertheless, when controlling for other variables in regression analyses, these associations with age and gender tended to change or disappear suggesting that some coping responses are conditional upon other factors (D'Haenens et al., 2013; Vandoninck et al., 2012; Vandoninck et al., 2013).

Coping was also associated with a range of psychological factors. Overall, it has been shown that youths with psychological difficulties were more likely to react in a passive (or even "fatalistic") manner, i.e., they were more likely to stop using the Internet and to hope that the problem would go away, and less likely to talk about their victimization. Specifically, higher emotional problems were associated with hoping that the problem would go away, lower conduct problems were connected with trying to fix the problem, and higher peer problems with trying to fix the problem and stopping to use the internet, while lower peer problems were linked with support seeking. Coping strategies were also associated with sensation seeking, self-efficacy, and digital skills. Those with lower sensation seeking more often talked to someone about the experience. Those with lower self-efficacy were more likely to stop using the internet and to delete the message, while those higher in self-efficacy were more likely to try to fix the problem, seek support, and to change their contact settings but less likely to hope the problem would disappear. The more digital skills reported, the more likely coping strategies specific to the internet were employed, i.e., deleting messages and blocking senders. There was also a connection to online activities of youth: the fewer activities they reported, the more likely they were to talk to somebody or to stop using the internet (D'Haenens et al., 2013; Vandoninck et al., 2012; Vandoninck et al., 2013).

Coping responses were also associated with being a bully/victim, both online and offline. Bully/victims more often felt guilty, tried to get back at the other person, and less often tried to fix the problem than those who were victims only (Görzig 2011; Hasebrink et al., 2011). Finally, coping responses were in all cases also associated with harm. The higher the intensity of harm victims reported, the more likely each of the strategies was employed (Cerna et al., n.d.; Vandoninck et al., 2012; Vandoninck et al., 2013).

Among the surveyed online risks within EU Kids Online, cyberbullying was found to be the most harmful experience. About one third (31%) of online victims reported being “very upset” by the incident while only 15% reported being “not at all upset.” Regarding the duration of harm, most youth (62%) got over it right away; however around 40% continued feeling upset for a few days or longer (Green & Brady 2013; Livingstone, Haddon, Görzig & Ólafsson 2011c; Livingstone et al., 2011b).

While some authors suggested that there is just a slight difference between 87% girls and 82% boys who found bullying at least somewhat (i.e., “a bit”) upsetting (Livingstone, Kalmus & Talves 2013), others stressed larger difference in terms of intense harm (i.e., being “very upset”), with 37% bullied girls reporting this intense harm in contrast to 23% of bullied boys (Livingstone et al., 2011b). The latter was supported by findings showing that girls were more likely to indicate being upset at all than boys (Livingstone et al., 2011c) and further analysis showed that the intensity of harm or the harm index is higher among girls than boys (D’Haenens et al., 2013; Vandoninck et al., 2012; Vandoninck et al., 2013). Findings for the relation of harm with age showed a mixed pattern. While the youngest in the sample (9-10 year olds) reported a lower proportion of those being “not upset at all” (12%) as opposed to the oldest in the sample (15-16 year olds; 17% “not at all upset”), the youngest also showed a lower proportion of being “very upset” (30%) as opposed to the oldest (34%) (Livingstone et al., 2011b). Not surprisingly, depending on the measurement of harm in some studies, authors have found that older victims experienced more harm (Vandoninck et al., 2012; Vandoninck et al., 2013), while in others, they found the opposite (Livingstone et al., 2011), and in some no significant relationship at all (Laurinavičius et al., 2012). Harm was also connected to psychological factors. Those higher in psychological difficulties, lower in sensation seeking, and with lower self-efficacy reported more or higher harm (D’Haenens et al., 2013; Laurinavičius et al., 2012; Livingstone et al., 2011; Vandoninck et al., 2012; Vandoninck et al., 2013). However, it is noteworthy that some authors found that among victims aged 9-10, those with higher self-efficacy reported more intense harm (D’Haenens et al., 2013), while others found no relationship between self-efficacy and harm when controlling for other factors (Laurinavičius et al., 2012).

Harm was associated with lower use of the internet (Livingstone et al., 2011), although this disappeared when controlling for other factors (Laurinavičius et al., 2012). Furthermore, a link of harm to online activities (D’Haenens et al., 2013) or digital literacy⁷ (Vandoninck et al., 2013) could not be found. Moreover, harm was connected with platforms and devices through which cyberbullying occurred. Some found that being bullied via IM was found to be more harmful than via other mediums (Staksrud et al., 2013). This finding was supported by others who found that harm was higher upon being cyberbullied on a mobile device but that this effect was mediated by cyberbullying occurring via IM or SNS (Görzig & Frumkin 2013). Finally, some authors found that those who had been bullied offline as well as those who had experienced less harm upon receiving sexual messages were less likely to experience harm from being bullied online arguing that “habituation” to risk experiences might have played a role (Laurinavičius et al., 2012).

⁷ Digital literacy was assessed by a composite of the variables digital skills and online activities.

Patterns of Cyberbullying Experiences and Responses

In general, the risk of experiencing cyberbullying and the responses to this experience show associations with an abundance of variables on the individual level as well as with interactions between those variables. This complex pattern of associations as presented above might be an indication that the variables on this level are perhaps the most important or else that merely the individual level is the one receiving the most attention by researchers.

Some findings are particularly worth mentioning. It has been shown that cyberbullying victimization as well as perpetration are strongly connected to offline bullying victimization and/or perpetration. Moreover, there is evidence that the roles of involvement in cyberbullying (i.e., bullies, victims and bully/victims) need to be differentiated in terms of their characteristics and behaviors as well as responses to cyberbullying experiences.

Furthermore, it is noteworthy that while some variables at the individual level show an equivalent relationship with risk and with harm, for others the relationship to harm is the inverse of their relationship to risk. Additionally, some show further associations with particular coping responses – possibly as a precursor or the result of feeling upset by the experience. There is generally some mixed evidence with regard to age. While older youth are more likely to be cyberbullying victims as well as cyberbullies, upon victimization younger victims were likely to stop using the internet while older victims were more likely to change their settings or fix the problem. For harm the association with age depends on what type of harm measure is being used and whether one focuses on those who are more likely to be the least upset (younger) among those who are upset or on those who are more likely to be not upset at all (older).

Some factors were connected to a higher occurrence of the risk of being victimized as well as a higher likelihood of being upset by the incidence, i.e., higher risk also meant higher harm. Among those were gender (girls), higher psychological difficulties, and use of SNS or IM. Furthermore, upon being victimized girls showed to be more likely to talk to someone while those with higher psychological difficulties were more likely to respond in a “fatalistic” manner. In contrast, other factors were connected to a higher risk but less harm. Among those factors were higher internet use, sensation seeking and self-efficacy, as well as being a victim of offline bullying. Those higher in self-efficacy also showed to be prone to react to victimization by trying to fix the problem. Furthermore, higher digital skills or ability beliefs were associated with a higher risk but also with more internet specific coping strategies. Generally, the more harm that was experienced by adolescents the more coping strategies were employed.

SOCIAL LEVEL

With regard to the social level, the project outputs captured the role of the young person’s immediate social environment. This section will begin reviewing factors associated with cyberbullying that relate to the young person’s social background followed by those associated with their parent or carer. Furthermore, mediation of the young person’s internet behaviors by parents, friends, and teachers and its relation to cyberbullying will be pointed out. Lastly, we review the role of support seeking (i.e., talking to someone upon being victimised) from parents, peers, or teachers.

The risk of being involved in cyberbullying was shown to be associated with various variables reflecting the social background. Generally, the risk of being involved in either online or offline bullying was slightly increasing with higher levels of socio-economic status (SES), although these differences were only small (Livingstone, Haddon, Görzig & Ólafsson 2011). However, among youth who were involved in online bullying, either as victim or bully, those with a higher SES were more often involved as a bully, while those with a lower SES were more often involved as victims (Görzig 2011). SES was also associated with harm, young people from lower SES families indicated more and a higher intensity of harm than those from a higher SES background. Finally, lower level of SES was connected with a less likely occurrence of some coping responses, specifically changing internet settings, responding by deleting a message or trying to fix the problem (D’Haenens, Vandoninck & Donoso 2013; Livingstone et al., 2011b; Vandoninck, D’Haenens & Segers 2012; Vandoninck, d’Haenens & Roe 2013). Beyond SES, youth from families which used minority languages at home, belonged to a discriminated against group, or were classified as being disabled showed higher experiences of being bullied online as well as harm when compared to the full sample. Furthermore, those from families which used minority languages reported bullying others online less often while those classified as being disabled bullied others online slightly more often. Moreover, with regard to coping strategies, youth more often sought support upon being victimized if they belonged to a discriminated against group or spoke a minority language at home (Livingstone et al., 2011).

Among the most prevalent parental worries concerning their child was the concern that their child could be bullied - together with concerns about school achievement, road accidents, and crime (Livingstone, Ólafsson, O’Neill & Donoso 2012). Children of parents who worried that their child might be contacted by a stranger or see inappropriate material online also showed higher incidences of being bullied online and subsequent harm. Furthermore, higher incidences of being bullied online and subsequent harm were associated with a parental perception about their child experiencing something upsetting online in general (Livingstone et al., 2011). Overall, 6% of parents and children reported that the youth had been bullied online. However, there were large discrepancies between parental and youth’s report of the young person’s victimization. Among youth who reported being bullied online, just about one third of their parents (29%) were aware of their child’s victimization while more than half (56%) reported that their child was not bullied online, and 15% answered “don’t know” in this matter. This discrepancy did not only concern victimized youth. For instance, 8% parents of non-victimized children thought their child had been bullied online, while the child reported the opposite. Furthermore, parents with a higher SES background showed a higher awareness about their child’s victimization. Parental awareness was also associated with factors from the individual level. Parents knew about the victimization more often if a victim was a girl, and was in the “mid-age” group (i.e., 11-14 years) (Green & Brady 2013; Livingstone et al., 2011b; O’Neill & Dinh 2012). Moreover, parents’ use of the internet was associated with their child’s involvement in online bullying. Children of parents who did not use the internet reported being victims of online bullying less often than was generally the case. However, these children also more often reported harm when they had experienced online bullying. Children of parents with lower confidence in using the internet were more often online bullies; there were no significant differences with regard to victimization or harm (Livingstone et al., 2011). The frequency of internet use reported by parents was also associated with coping strategies victims used. Children of parents who were using the internet less frequently were less likely to hope that the

problem would go away, but they were also more likely to stop using the internet after the victimization and more likely reported the problem online (Vandoninck et al., 2013).

A lot of attention has been given to the link between parental mediation of their children's internet use and encountering online risks and harm. Importantly, mediation strategies could be either underlying factor of but also a response to a young person's victimization experience. It has been shown that restrictive mediation is connected to lower online risks, including cyberbullying (Duerager & Livingstone 2012). Moreover, more intense harm was reported by children with parents who mediated their internet safety, restricted their internet use, used technical mediation, and who were less active in mediating internet use (D'Haenens et al., 2013). Mediation strategies in general were also found to be associated with the coping strategies victims applied. Parental mediation of internet use increased the odds of victims actively trying to fix the problem, but it also decreased the odds of deleting the messages and blocking the sender. Parental mediation of internet safety was connected to both active and passive responses, as it increased the odds of talking to somebody and blocking the sender, but also of hoping that the problem will go away. Parental restrictive mediation lowered the odds of hoping that the problem would go away, but it also increased the odds of changing the settings. Children whose parents applied technical mediation were less likely to delete the messages, change their settings, and more likely to stop using the internet; on the other hand, they also were more likely to talk about the experience to somebody and reported the problem online. Parental monitoring showed the opposite effect, it increased the odds of deleting the messages but decreased the odds of talking to someone about the experience. Peer mediation took place among those who were more likely to talk to their peers about their victimization. While mediation by peers has been associated with higher odds of deleting messages or changing settings as coping responses, mediation by teachers had the opposite association with these two coping responses (Cerna, Machackova & Dedkova, n.d.; D'Haenens et al., 2013; Vandoninck et al., 2013).

Talking to someone or seeking support upon being bullied online is a specific response, which is connected to factors on both the individual and the social level. While we have presented the role of talking to someone at all about the experience as an individual level factor, we will differentiate to whom the young person talked to in this section as it reflects the specific social interaction. However, factors relating to support seeking associated with specific mediation techniques that have been outlined above will not be repeated here. Generally, upon being bullied online a young person was most likely to have talked to his or her parents and peers and less likely to a sibling, another trusted adult, a teacher, or someone else whose job it is to help children (Livingstone et al., 2011b). Furthermore, some other social level factors were also connected to whom youths talked to. Young people who perceived their parents to be more aware of their internet activities were more likely to have talked to their parents when having been bullied online. Moreover, as shown in the individual level section, youths from families which used minority languages at home were more likely to seek support; however, this was shown to be due to the fact that they were more likely to talk to their parents but not more likely to talk to any of the other groups asked about. Furthermore, a general tendency to talk to peers about bothersome experiences was associated with higher odds of seeking support from peers after online victimization, but lower odds of talking to parents about online victimization. Moreover, there were some differences associated with individual level variables in terms of whom youths talked to upon being bullied online. Younger victims were more likely to talk to parents or siblings and less likely to talk to peers, while older victims were less likely to talk to

teachers. Girls were more likely to report talking to friends and were almost twice as likely as boys to talk to both, parents and peers than to no one, even when accounting for age, harm, or parental and peer mediations (Cerna et al., n.d.; Livingstone et al., 2011b).

The importance of social-level factors has been demonstrated via associations with youth's risk experiences and responses to victimization. In terms of social background, there was generally an association of social disadvantage (e.g., low SES, being from a discriminated against group) with the experience of cyberbullying victimization as well as harm from being a cyberbully victim. A higher incidence of risk and harm was also generally associated with higher parental worries or awareness about their children's internet use, risk, and harm. However, a large proportion of parents remain unaware of their children's risk experiences. Parental awareness also varies with socio-demographic factors, of which some are associated with a higher likelihood of the risk (e.g., being a girl, having a low SES). Some parental behavior is simultaneously associated with a lower occurrence of the risk of cyberbullying victimization and a higher occurrence of subsequent harm. This inverse relationship of risk and harm was found for children of parents who did not use the internet and those who applied restrictive mediation strategies. Youths also showed differential patterns of coping responses in association with social level factors, such as SES, factors associated with social disadvantage, frequency of parental internet use, and mediation by parents, peers, and teachers. Moreover, there have been notable differences in whom youths tended to confide in or were able to seek support from upon being bullied online, some of which were associated with other social or individual level variables.

CULTURAL LEVEL

This section commences reporting cross-national differences in the prevalence of risk and harm from cyberbullying. This will be followed by cross-national differences in the strengths or direction of variables' associations with cyberbullying. Lastly, factors that have shown to be correlates of the cross-national differences in cyberbullying prevalence will be presented.

The proportion of youth who have been bullied online or been cyberbullied has been shown to vary across countries. These rates were highest in Romania (14% or 15%) and Estonia (13% or 16%), and lowest in Portugal and Italy (both 2% and 3%, respectively) (Görzig 2013; Livingstone, Haddon, Görzig & Ólafsson 2011; Lobe, Livingstone, Ólafsson & Vodeb 2011). Applying multilevel logistic regression analysis it was shown that the odds of cyberbullying victimization vary significantly across countries and that 7% of the variance in cyberbullying victimization can be explained by aspects at the country level (Görzig 2013). In terms of online or cyberbullying perpetration, there has been a similar variation (Görzig & Ólafsson 2013; Görzig 2011; Lampert & Donoso 2012). A difference in prevalence rates between countries was also shown in terms of harm experienced from online bullying. It was shown that in most countries the proportion of youths who indicated to be upset by the experience out of those who have been bullied online varied between 70% and 90%, while Finland and Bulgaria were exceptions (less than 60% of those bullied indicated to be upset by it). The highest proportions of youth who have been upset due to online bullying were reported in Denmark, the UK, Sweden, and Romania (Lobe, Livingstone, Ólafsson, & Vodeb 2011).

Various analyses conducted on the EU Kids Online data found country differences in the associations of variables with cyberbullying. Country differences were found in the association of cyberbullying victimization and gender. In most countries more girls than boys experienced cyberbullying victimization (Turkey was a notable exception). However, these gender differences were not always significant (see Figure 2) (Görzig 2013).

Moreover, upon conducting the same logistic regression analysis for each of the 25 countries, it was found that in Spain, Finland and Lithuania, the child’s gender (i.e., girls) was the most relevant factor among others⁸ predicting online bullying victimization. In addition, there were differences in the association of internet usage to online bullying across countries; (higher) usage was the most important predictor in Greece, Hungary, Italy, and Slovenia. Moreover, (more) risky online activities were found to be the most relevant predictor in Bulgaria, Denmark, Poland, Portugal, and Sweden (Lobe, Livingstone, Ólafsson & Vodeb 2011). Risky online activities also showed significant cross-country variations as a predictor of cyberbullying. Cyberbullying had the weakest relationship to risky online activities in Romania and the UK, and the strongest in the Netherlands and Bulgaria. It was shown that in countries with fewer cyberbullies, cyberbullying was more strongly related to risky online activities (Görzig & Ólafsson 2013). In terms of platforms used, it was shown that among cyberbully/victims the odds that they had been bullied via a mobile device (“on-the-go”) differed across countries. This was less likely in Bulgaria and Denmark, and more likely in Sweden when compared to the odds across all countries (Görzig & Frumkin 2013).

Figure 2. Percentage of cyberbullying victims by country and gender. Data are weighted. Whiskers represent 95% confidence intervals. Gender differences are significant in Sweden, Denmark, Norway, the Netherlands and Spain. Adapted from (Görzig 2013) with the author’s permission.

As indicated earlier in this chapter when examining the individual level, victimization and perpetration of cyberbullying go hand in hand. Similarly, as the number of youths who reported having been bullied increases in a country so does the number of youths who admitted to having

⁸ The following variables were included in the analysis: gender, “has sent a nasty or a sexual message”, “I get very angry and often lose my temper”, “time spent on the internet (minutes)”, “risky online activities”, “online persona.”

bullied others. This was demonstrated by a significant country level correlation between bullying and being bullied online. Incidences were highest in Estonia, Sweden, and Romania, and lowest in Italy, Portugal, Turkey, and Greece (Görzig 2011). Whilst controlling for demographic and psychological factors, multilevel logistic regression analysis confirmed that the association between victimization and perpetration varied significantly by country, ranging from the weakest (but still strong) associations shown for Romania and Cyprus to the strongest associations for Italy, Norway, and the Czech Republic (see Figure 3) (Görzig 2013). In addition, in the majority of countries, the factors that were most relevant in explaining online bullying victimization were online bullying perpetration or sending sexual messages to others (Lobe, Livingstone, Ólafsson & Vodeb 2011).

Figure 3. Country variations in predicting cyber-bullying victimisation. OR = Odds Ratio; the bar chart shows the lowest odd ratio across countries in dark grey fill and the highest in light grey fill; the table shows the likelihood ratio test statistics indicating the significance of cross-country variations per variable as well as the countries with the highest and lowest odds ratios upon significant variation; adapted from (Görzig 2013) with the author's permission.

Furthermore, a study investigating the proportions of cyberbullies among bullies in general (i.e., face-to-face, via the internet or mobile phone) found that in Greece, the prevalence of cyberbullies among cyber and face-to-face bullies was significantly lower than the prevalence across all countries, while they were significantly higher in Romania, Belgium, Estonia, and Sweden (Görzig & Ólafsson 2013). In addition, significant cross-country variation in predicting cyberbullying victimization was shown for age, gender, self-efficacy, and psychological difficulties but not for sensation seeking (see Figure 3) (Görzig 2013). These differences in associations across countries for age, gender, and psychological variables with cyberbullying victimization as well as the link between cyberbullying perpetration and victimization have been supported elsewhere (Vazsonyi, Machackova, Sevcikova, Smahel & Cerna 2012).

Finally, in terms of correlates on the social level it was found that parental awareness of their child having been bullied online differed across countries. Parents were least aware in Cyprus, Hungary, Italy, Greece, and Romania, and most aware in the Netherlands and Finland (Livingstone et al., 2011b).

A handful of studies have investigated whether any factors on the country level (e.g., policy regulations, national statistics, cultural norms and attitudes) might be associated with differences in the proportion of cybervictims across countries. Linking with data from the European Social Survey (2008; countries excluded from the analyses: Austria, Italy, Lithuania), it was found that a higher incidence of cyberbullying can be partially explained by country-level variables, such as a country's negative average attitudes towards equality, lower average religiosity ratings, and higher crime rates, with all three factors explaining a significant amount of country variation in cyberbullying (see Figure 4) (Görzig 2013).

Figure 4. % Cyberbullying victims and country-level indicators by country. Variables explained a significant amount of country variation in cyberbullying (all $\chi^2(1) = 4.5$ to 4.9 ; p 's $< .05$). ISO 3166-1 alpha-2 country codes are used (International Organization for Standardization, 2004). Adapted from (Görzig 2013) with the author's permission.

Another study investigating the sample of 10-14 year old youths from 24 countries (excluding Turkey) found that countries with higher rates of online bullying were more likely to have a higher incidence of unnatural child deaths (e.g., accidental deaths, suicide deaths, various forms of assault). At the same time, the prevalence of exclusively online bullying was not correlated with the national prevalence rate of depressive symptoms nor were depressive symptoms associated with the rate of unnatural child deaths, excluding depression rates as a possible explanation for the link between countries' unnatural child deaths with online bullying (Fu, Chan & Ip 2014).

Furthermore, comparing harm experienced from online bullying, an analysis used a threefold country classification of "high use, high risk," "medium use, medium risk," and "high use, medium risk," based upon daily internet use and exposure to at least one online risk (Livingstone et al., 2011b). It was found that the proportion of youths who reported online bullying to be more severely upsetting was lower in the "high use, high risk" cluster when compared to the other two country clusters (Vandoninck et al., 2013).

Lastly, a study tested whether countries' broadband penetration (i.e., the percentage of households using broadband connections; Eurostat, 2009) and mobile penetration (i.e., mobile phones per hundred inhabitants; Eurostat, 2008) would be related to the proportion of cyberbullies among bullies (i.e., face-to-face and cyberbullies). It was found that countries' mobile penetration could partially explain cross-country variation in cyberbullying; however, this was due to the fact that the relationship between risky online activities and cyberbullying varied across countries in line with their mobile phone penetration, i.e., the relationship between

risky online activities, and cyberbullying was stronger in countries with a higher mobile phone penetration (Görzig & Ólafsson 2013).

In conclusion, we find ample evidence of the variation in cyberbullying and its correlates across countries. While only 7% of the variance in the prevalence of cyberbullying victimization can be explained by the country level, the strengths of other variables that explain further variance in cyberbullying has also shown to vary across countries. These variables consist of demographic factors (age, gender), use and activities (usage, risky online activities, use of a mobile device), psychological factors (psychological difficulties, self-efficacy but not sensation seeking), parental awareness of their child's cyberbullying victimization, and youths being cyberbullies themselves.

We also found that there were some factors that showed a relation to higher prevalence rates of cyberbullying victimization on a country level (i.e., negative attitudes towards equality, lower religiosity, higher crime rates and higher unnatural child deaths). More studies exploring ostensible explanations for the cross-country variations found have yet to be conducted. However, what we can say with certainty is that the cultural or country level does play a role in the occurrence of cyberbullying even if, as indicated by the low explanatory variance across countries, it is one role among other factors and levels of the socio-ecological system.

CONCLUSION

The evidence from the EU Kids Online II project connected several factors of the individual, social, and cultural levels with cyberbullying experiences and the vulnerability to harm following victimization. Factors for which research outputs from EU Kids Online data have demonstrated an association with cyberbullying are listed for each of the levels in Table 1. However, it must be noted that more complex patterns of findings are reported in the corresponding result sections of this paper and that not listed factors do not necessarily demonstrate a lack of association but might rather show a lack of research findings concerning those factors. Hence, the inclined reader is asked to exercise caution when using the table as a stand-alone output of results. A more detailed discussion of the main findings and conclusions follows below.

Concluding this chapter, we will suggest some particularly salient factors that have been identified as risk and protective factors for the experience of cyberbullying across the levels of the socio-ecological system. We will then allude to those factors which were associated with both the risk of the experience and subsequent vulnerability to harm. Next, we will refer to factors that are linked with effective coping responses. Subsequently, we will suggest factors that could aid resilience in terms of vulnerability to harm. We will close by giving some brief recommendations for possible intervention and prevention efforts.

The findings uncovered that online bullying is a rather low-prevalence phenomenon in Europe (6% for victims and 3% for bullies). While these rates are in line with prevalence rates reported by surveys using similar methodologies, the prevalence rates of cyberbullying across other studies have shown large variation depending on the definitions, measurements, samples, and time periods covered, with percentages ranging from 1% to well over 50% (cf. Livingstone & Smith, 2014). The prevalence reported in this review and most of the literature, however, does suggest that contrary to some recent media portrayals, cyberbullying is not occurring at epidemic levels (Sabella, Patchin, & Hinduja, 2013).

Table 1. Factors associated with cyberbullying in research of EU Kids Online data by socio-ecological level

Individual	Gender (girls) Age (older) Daily internet use Time spent online Platforms (SNS, IM) Data misuse Viewing web content with suicide and self-harm Offline victimization Cyberbullying Psychological difficulties Self-efficacy Sensation seeking Ostracism	Age (older) Time spent online ^a Platforms (SNS) ^a Risky online activities ^a Internet ability beliefs ^a ‘Online persona’ ^a Excessive internet use Viewing web content with self-harm Offline risks Offline bullying Cyberbullying victimization Psychological difficulties Self-efficacy Sensation seeking	Gender (girls) Daily internet use (-) Platforms (SNS, IM) Offline victimization (-) Psychological difficulties Self-efficacy (-) Sensation seeking (-)

Notes: If not indicated otherwise the direction of association is positive and the reference group consists of not involved youth. (-) indicates negative associations. ^a indicates factors for which the reference group was offline bullying. The absence of listed factors either indicates that there was no research output or no association has been found. More complex patterns of factors and factors with ambivalent research results are not included in the table. Please refer to the corresponding chapter sections for details.

In terms of the experience of cyberbullying, several risk and protective factors in cyberbullying have been identified. Cyberbullying experiences were more common among older youths, while cybervictimization was more common among girls and no gender differences emerged for the prevalence rates of cyberbullying others. These findings are both supported and conflicting based on evidence from the literature, especially given the mixed findings concerning age and gender differences in cyberbullying (Kowalski, Giumetti, Schroeder, & Lattanner, 2014; Tokunaga, 2010). This could be due to similar methodological issues as for the prevalence rates in general and/or some of the described differential demographic patterns regarding internet use and activities, which were also uncovered within EU Kids Online or more recently the *Net Children Go Mobile* project (Livingstone, Haddon, Görzig, & Ólafsson, 2011; Mascheroni & Ólafsson, 2014).

In line with previous findings connecting cybervictimization with poorer psychological outcomes, poorer quality of social relationships and/or social disadvantage (Cappadocia, Craig, & Pepler, 2013; Kowalski & Limber, 2013; Vandebosch & Van Cleemput, 2009; Whittle, Hamilton-Giachritsis, Beech, & Collings, 2013), cybervictimization has been found to be associated with higher ostracism and psychological difficulties as well as with some social disadvantage. However, experiencing cybervictimization was also linked with higher self-efficacy and sensation seeking.

Some of the factors above were also connected to the perpetration of cyberbullying but there were also some differences. Cyberbullies seemed to be somewhat less likely to be socially disadvantaged. Psychological factors were generally similar for cyberbullies and victims; however, cyberbullies did not show enhanced ostracism or more peer problems as cybervictims. Moreover, bully/victims differed from victims and bullies. Confirming previous research for youths involved in both of these roles, psychological difficulties seemed to be generally exacerbated (e.g., Beckman, Hagquist, & Hellström, 2012; Gradinger, Strohmeier, & Spiel, 2009; Ybarra & Mitchell, 2004).

While these findings suggest that it is important to differentiate the roles of cyberbullying involvement, they also indicate the similarities between those roles. Indeed, various findings

showed that there is a strong association between bullying perpetration and victimization, online and offline; this is consistent with findings elsewhere (e.g., Festl, Scharkow, & Quandt, 2014; Menesini & Spiel, 2012; Mishna, Khoury-Kassabri, Gadalla, & Daciuk, 2012; Waasdorp & Bradshaw, 2015).

This association between cyberbullying and offline bullying, as well as between victimization and perpetration, indicates a possible common tendency to a general risk of experiencing bullying among adolescents. Given the further findings concerning the association of cyberbullying involvement with other types of risk experiences, online and offline, this tendency to experience risks could be extended to other types of risks. Indeed previous research has suggested that those who are prone to risky behaviors in one domain would also be so in others (Carson, Pickett, & Janssen, 2011; Guilamo-Ramos, Litardo, & Jaccard, 2005; Jessor, 1991). Explanatory accounts in relation to adolescents have linked this phenomena to a combination of a lack of impulse control and enhanced sensation seeking (Steinberg et al., 2008; van Nieuwenhuijzen et al., 2009) - a notion further supported by the evidence given in this review as well as research on internet risks (e.g., Baumgartner, Sumter, Peter, & Valkenburg, 2012).

Despite this association between the offline and the online, for bullying as well as for risk experiences in general, the findings also reveal some behavioral factors that are solely connected to bullying experiences online. Coherent with previous research (e.g., Hinduja & Patchin, 2008; Mishna et al., 2012; Smith et al., 2008; Sticca, Ruggieri, Alsaker, & Perren, 2013), it was shown that higher and more frequent internet use were connected with cyberbullying victimization as well as perpetration. However, more online activities as well as related beliefs, such as digital skills or internet ability beliefs, were mainly connected with cyberbullying perpetration. The latter finding elaborate on previous evidence that those with more advanced digital skills might engage in more “deviant” cyber-activities (Vandebosch & Van Cleemput, 2009). Furthermore, higher digital skills among perpetrators link with the notion of a *power imbalance* eminent in the definition of bullying, which has been suggested to occur in cyberbullying via differential abilities in digital skills – as opposed to face-to-face bullying where power is often linked to physical strength or peer group popularity (Slonje, Smith, & Frisé, 2012). However, we also find that particular affordances of the internet or mobile devices interact with individuals’ characteristics. For example, while SNS use appears to amplify cyberbullying experiences this is particularly the case among girls, perhaps because cyberbullying via SNS tends to take the form of relational aggression which has been more commonly observed in girls (Beckman, Hagquist, & Hellström, 2013; Coyne, Archer, & Eslea, 2006).

Extending internet use across other levels of the socio-ecological system, we find that not only are youths’ cyberbullying experiences connected to their own (higher) internet use but also to (higher) parental internet use. In contrast, parental restrictions on their children’s internet use were shown to be linked with a decrease in youths’ cyberbullying experiences (see also Mesch, 2009; Navarro, Serna, Martínez, & Ruiz-Oliva, 2012).

Taking the cultural level into account, findings showed that the prevalence of cyberbullying victimization varied across the countries studied in the EU Kids Online survey. The different incidences of cyberbullying experiences could partially be explained by cultural factors, such as overall negative attitudes towards equality, religiosity ratings, or crime rates. However, in line with other cross-national evidence (Genta et al., 2012) differences among individuals were generally considerably larger than the differences across different European countries.

Possibly, the analysis of smaller units of more adjacent cultures (i.e., communities) might yield more explanatory power as has been suggested in the case of bullying research (Swearer et al., 2006). Nevertheless, findings also showed that the differences between certain individual factors varied by country (e.g., age, gender, self-efficacy, and psychological difficulties in predicting victimization). Moreover, country variation has been found for engagement in risky online activities and internet use as well as for the link between victimization and perpetration. Yet, a strong theoretical framework to explain differences in the cultural level is still lacking.

Generally, a large array of factors across the levels of the socio-ecological system has been uncovered in relation to the risk of cyberbullying experiences among adolescents. However, as pointed out earlier in this review, we consider it crucial to differentiate between risk factors and factors underlying the vulnerability to harm (see also, Livingstone & Görzig, 2014; Livingstone & Smith, 2014). According to the EU Kids Online's findings, cyberbullying is one of the most harmful negative online experiences. Yet, not all youths who were victimized were vulnerable to experience harm or more intense harm. There were several common factors connected with both increased risk and harm, e.g., being a girl, having psychological difficulties, and social disadvantage. However, other factors, such as higher sensation seeking, self-efficacy, internet use (parents' and youths'), and being bullied offline as well as less restrictive mediation by parents were related to increased risk but at the same time they were associated with less harm. Further, in countries where youth used the internet more they also experienced higher risk but were less vulnerable to harm.

Hence, it is possible that while some factors increase exposure to risks, the exposure to some (risky) experiences, along with the associated psychological factors, might help to build resilience toward harmful consequences. This notion is supported by the psychological literature suggesting that exposure to risk and positive adaptations are prerequisites for resilience building (Coleman & Hagell, 2007; Luthar, Cicchetti, & Becker, 2000). The term "risky opportunities" has been applied in this context (e.g., Hasebrink, Görzig, Haddon, Kalmus, & Livingstone, 2011; Livingstone, Haddon, Görzig, & Ólafsson, 2011), referring to the fact that activities that are related to risks can simultaneously offer opportunities. In relation to internet use, the same activities which might lead to exposure to risk (e.g., cyberbullying) might also provide opportunities (e.g., digital skills) which are further connected with a lower vulnerability to harm and thus aid resilience (Livingstone, Haddon & Görzig 2012; Livingstone et al., 2011c).

More or less vulnerability to harm was also connected to the application of specific coping strategies. It should be noted that the interpretation of this link must be cautious, as harm can be both precedence and consequence of coping. Nonetheless, according to the findings, we could argue that the more harm youths endured, the more they were willing to react to the risk experience, either in an active or in a passive manner. The data demonstrated various links between individual and social level factors and coping responses. Talking about the experience of being a victim of cyberbullying was one of the most prominent (and often recommended; Dooley, Gradinger, Strohmeier, Cross & Spiel 2010) coping responses. Consistent with prior research (Perren et al., 2012), EU Kids Online findings showed that youths most often confided in peers and parents. Overall, less passive responses (e.g., hoping the problem would go away) and more active ones (e.g., trying to fix the problem) were associated with higher self-efficacy and digital skills, and lower psychological difficulties as well as a less likely involvement as a bully/victim – all factors that have also been linked with less vulnerability to harm online (e.g., Livingstone et al., 2011c). Furthermore, "blocking the sender" was reported to be the most

effective internet-specific coping strategy. In addition, “blocking the sender” was associated with more internet activities among youths which – as pointed out above – are further linked with more digital skills and subsequently also less harm.

Notably, it was generally demonstrated that the factors above which were connected with more effective coping responses were often the same factors associated with a lower vulnerability to harm.

Hence, if these factors were addressed this could potentially enhance coping with the risk experience as well as lessen vulnerability to harm. However, there were also some divergences between coping and harm responses. For example, while those higher in sensation seeking also experienced less harm they were less likely to talk to someone after experiencing victimization. This suggests that, although some personal characteristics can decrease vulnerability to harm, they can sometimes also be associated with a reluctance to use strategies which would be otherwise considered helpful.

Overall, we find reciprocal relationships between risky opportunities, coping and resilience which are often reflected in corresponding relations of factors across all levels of the socio-ecological system. Given the presented evidence as well as the support provided by the literature we suggest considering the complex interplay between opportunities, risks, and harm, and their associated factors on and across the different levels of the socio-ecological system to address cyberbullying intervention or prevention efforts. Importantly, as demonstrated in this review, there is considerable variation in factors linked to cyberbullying (risk and harm) on all levels as well as some interactions of factors between levels. Hence, in concert with others (Jones, Mitchell & Walsh, 2013; Swearer & Espelage 2011), we propose that any programs should be tailored to the specific target population taking into account their individual, social and cultural background.

AUTHORS NOTE

This work was supported by the project “Employment of Best Young Scientists for International Cooperation Empowerment“ (CZ.1.07/2.3.00/30. 0037) co-financed from European Social Fund and the state budget of the Czech Republic.

This chapter draws on the work of the ‘EU Kids Online’ network funded by the EC (DG Information Society) Safer Internet Programme (project code SIP-KEP-321803).

Chapter 18

THE ROLE OF ETHNICITY AND CULTURE IN CYBERBULLYING EXPERIENCES AMONG YOUTH

Guadalupe Espinoza^{1,*} and Jaana Juvonen²

¹California State University, Fullerton, California, US

²University of California, Los Angeles, California, US

INTRODUCTION

Despite growing research documenting that ethnic minority youth (e.g., Asian American and Latino youth) use the Internet and other forms of online communication tools at higher rates than White youth (Madden, Lenhart, Duggan, Cortesi, & Gasser, 2013; Rice and Katz, 2003), there is little research on cyberbullying among groups other than White youth in the United States. Thus, the role of ethnicity, and more broadly, the role of culture in cyberbullying, are not well understood. For example, a critical review of research on cyberbullying published within the last decade synthesized the role of key demographics, such as age and gender, but did not discuss ethnic or cultural issues (Tokunga, 2010). Yet, as young people from diverse ethnic backgrounds are electronically connected to their peers online at increasing rates across the globe, it is important to try to identify the extent to which their online behaviors and experiences are universal versus culturally nuanced. The existing studies that include youth of various ethnic backgrounds are typically comparative studies examining rates of cyberbullying involvement (i.e., perpetration and victimization) across ethnic groups within the US (e.g., Bauman, Toomey, & Walker, 2013). There are fewer cross-cultural and cross-national comparative studies (e.g., Li, 2008). An increasing number of cyberbullying studies, however, are including multiethnic samples. There are also a growing number of studies examining within-group differences and processes with samples from a single ethnic minority group (e.g., examining generation status differences among Asian or Latino youth).

* Corresponding Author's Email: guadespinoza@fullerton.edu

Together these studies can help us better understand questions such as:

- Are youth from Western countries or particular ethnic groups at higher risk of being involved in cyberbullying as a bully or a victim?
- Do risk factors for cyberbullying involvement have a similar impact across various groups?
- Do presumed protective factors, such as family connectedness and parental monitoring, function similarly regardless of ethnicity and culture?

The overarching goal of the current chapter is to describe current research on the role of ethnicity and culture in cyberbullying experiences among youth. We will start with a rationale of why it is particularly timely to study cyberbullying incidents among ethnic minority and culturally diverse youth. Next, a description of comparative and cross-cultural studies examining differences in cyberbullying involvement rates and trends will be provided. Examples of research focusing on within-group differences among ethnic minority youth and cross-cultural research examining processes involved in cyberbullying outcomes will be reviewed next. The chapter concludes with recommendations for future research to better address the role that ethnicity and cultural background plays in cyberbullying behaviors and experiences among youth.

INCREASING USE OF ONLINE COMMUNICATION TOOLS ACROSS ETHNIC GROUPS

For many adolescents, the Internet and electronic devices are a central and indispensable part of their daily lives. Internationally, the percentage of households with a personal computer is rising and overall, young people have increased their online connectivity (Dutta & Bilbao-Orsorio, 2012). In the United States, recent estimates suggest that 95% of teens (ages 12 to 17) are connected online and two-thirds go online every day (Madden, Lenhart, Duggan, Cortesi, & Gasser, 2013). Adolescents spend between eight to nine hours a day using different electronic communication devices (Rideout, Foehr, & Roberts, 2010). Although youth multi-task across electronic devices and platforms (Carrier, Cheever, Rosen, Benitez, & Chang, 2009), it is evident, that many adolescents spend as much time with technology as they do with their family or school. Although adolescents use communication technology for multiple purposes, such as entertainment and education, communication with peers likely represents the most pervasive use of technology.

In recent years, the digital divide that once existed within the US based on race and socioeconomic status has been shrinking and per some estimates, ethnic minority youth use online communication devices at similar rates as White youth (Chakraborty & Bosman, 2005; Eamon, 2004). In particular, the gap in Internet use between Latino and White adolescents has declined considerably. According to results from a national study of over 2,000 youth, total media exposure is higher for Latino adolescents compared to White teens (Rideout, Foehr, & Roberts, 2010). Latino youth spend more time talking and texting compared to White youth (2 hours and 19 minutes and 1 hour and 47 minutes, respectively) and spend more overall time on the computer. In comparisons between White and Black youth, White youth are more likely to

access the Internet compared to Black youth (98% versus 92%, respectively). However, Black teens are more likely to access the Internet mostly via their cell phones compared to White teens, which suggests that they may be more likely to be constantly connected online (33% versus 24%, respectively; Madden, Lenhart, Duggan, Cortesi, & Gasser, 2013). Estimates also indicate that compared to White, Black, and Latino youth, Asian and Pacific Islander children and adolescents (ages 3-17) have the highest access to computers and the Internet at home (Child Trends, 2013).

Thus, although the narrowing of the digital divide is promising, inasmuch as it shows some equality across groups in access to technology, it also means that ethnic minority youth are likely to experience the negative “costs” of being connected online (e.g., involvement in cyberbullying).

DIFFERENCES IN RATES OF CYBERBULLYING PERPETRATION ACROSS ETHNIC AND CULTURAL GROUPS

Much like the literature on incidents of school bullying (e.g., Espelage & Swearer, 2003), there is no clear consensus of whether particular ethnic groups within the US are at higher risk of being involved in cyberbullying as perpetrators or victims. However, in cyberbullying research, this lack of consensus is largely due to the limited number of studies that have tested for such differences. For example, there are two studies suggesting that African-American youth were more likely to act as online perpetrators compared to adolescents from other ethnic backgrounds in the US (Low & Espelage, 2013; Wang, Iannotti & Nansel, 2009). Consistent with these findings, one study based on British secondary school students found that those students who self-identified as Black-Black British were more likely to be perpetrators compared to White-British students and Asian-British students (Fletcher, Fitzgerald-Yau, Jones, Allen, Viner, & Bonell, 2014). Although these findings parallel findings of some studies regarding school-based bullying perpetration in the US (e.g., Juvonen, Graham, & Schuster, 2003; Wang, Iannotti, & Nansel, 2009), all three cyberbullying studies were based on self-reports of online bullying. Moreover, there is at least one large scale study conducted in England where no reliable ethnic differences were found in cyberbullying perpetration among 11 to 16 year old White, Asian, Black, and Mixed students (Smith, Thompson, & Bhatti, 2012). Thus, it may be premature to conclude whether any one ethnic group within the US or UK might be more likely to aggress against their peers online.

Equally few studies have examined whether there might be cross-cultural differences in levels of cyberbullying perpetration. In one of the first cross-cultural studies on cyberbullying, Li (2008) found Canadian students were more likely to be cyberbullies compared to Chinese students. In a study examining differences between high school students in the US, and Japan, students from the US reported more cyberbullying than students in Japan (Aoyama, Utsumi, & Hasegawa, 2011). Barlett and colleagues (2014) also found that US adolescents reported more cyberbullying involvement as perpetrators compared to Japanese adolescents. Thus, the handful of studies that have examined cultural differences in levels of cyberbullying perpetration have rather consistently shown higher reports from students living in the United States and Canada compared to Chinese and Japanese students or Australian and many European youth. These findings are consistent with research on general aggression rates (e.g., Bergeron & Schneider,

2005) and suggest that cyberbullying perpetration may reflect general patterns of cultural differences.

DIFFERENCES IN RATES OF CYBERVICTIMIZATION ACROSS ETHNIC AND CULTURAL GROUPS

Although some cultures or ethnic groups might be higher on aggression, including cyberbullying, this does not necessarily mean that there are also more victims (few bullies can target lots of others, just as many bullies may target the same few individuals). Indeed, for online victimization, comparative studies show fewer consistent patterns. Among a large sample of over 15,000 adolescents in the US, those categorized as “other” which included, for example, Native Hawaiian and Asian adolescents, reported greater online victimization than White, Latino, and African American teens (Messias, Kindrick, & Castro, 2014).

Another study revealed that White youth were more likely to be victimized online compared to Latino youth (Kupczynski, Mundy, & Green, 2013). Meanwhile, other studies find no differences in rates of online victimization across various ethnic groups. For example in a study that included youth from American Indian, Black/African American, White, and Latino ethnic backgrounds, no differences were found for rates of online victimization and perpetration (Bauman, Toomey, & Walker, 2013; see also Sontag, Clemans, Graber & Lyndon, 2011). Compared to studies examining ethnic differences within a culture, there are even fewer studies testing differences across cultures. In the aforementioned study on Chinese and Canadian students, rates of cybervictimization were found to be similar for both groups of students (Li, 2008). In a study comparing the victimization experiences of English, Spanish, and Italian youth, Ortega and colleagues (2012) found that English adolescents were more likely to be affected (rather than nonaffected, based on cluster analyses) compared to Spanish and Italian youth. Clearly, it is difficult from the limited comparative studies to draw firm conclusions regarding rates of cybervictimization across various ethnic groups within the US and cross-culturally. Moreover, it is unclear why certain ethnic or cultural groups might be targeted more than others.

STUDYING PROCESSES ACROSS GROUPS AND WITHIN-GROUP DIFFERENCES

In addition to examining simple differences in rates of involvement, studies have also investigated whether the impact of cyberbullying varies depending on ethnic or cultural background. For example, do Latino, White, or African American students experience online victimization similarly? Studying the correlates of cybervictimization can also shed light on whether the same factors (e.g., close friends) serve a protective function by alleviating signs of distress across diverse groups of youth. For example, Black youth have been found to have more close friends outside of school compared to White youth (Clark & Ayers, 1992); thus, these out-of-school friendships might protect Black youth from the emotional pain associated with cybervictimization.

Although very few studies have tested these more complex research questions, some potential processes have been examined, including family factors, such as parental solicitation and parental control (Shapka & Law, 2013), and group-level processes such as social reinforcement for cyberbullying (Barlett et al., 2014), as well as individual factors including proactive and reactive motivations for engaging in aggression (Shapka & Law, 2013). We highlight some of these studies to showcase the types of research questions that can be addressed and the potential value of such findings.

One recent Canadian study found different patterns in the ways that parenting behaviors related to cyberbullying perpetration between East Asian and European Canadian youth (Shapka & Law, 2013). Specifically, higher levels of parental solicitation (e.g., extent to which teens tell their parents what they do on the Internet) and lower levels of parental control (e.g., extent to which teens report that their parents limit the things they can do online) were more closely related to cyberbullying perpetration among East Asian adolescents, compared to European adolescents. One conclusion made by the authors is that parental solicitation may not have the same protective effects among adolescents from East Asian descent as has been found with White youth. In fact, when East Asian parents actively gained information through requests to the child, this was linked with increased levels of perpetration. These type of differences suggest that it is important to consider ethnic or cultural differences when trying to understand risk and protective factors for cyberbullying. This view is also consistent with the conclusion by Shapka and Law (2013), who underscore that relying on a one-size-fits-all prevention approach for cyberbullying based on the majority culture may be ineffective for particular ethnic minority groups.

In addition to communication with parents, there is evidence suggesting that online peer dynamics might also vary across ethnic groups. In a short-term longitudinal study among older adolescents, Barlett and colleagues (2014) found that compared to Japanese youth, US adolescents (predominately White) were more sensitive to positive attitudes about and reinforcement for their online bullying. That is, teens who reported more positive reinforcement and who held more positive attitudes toward cyberbullying at wave 1, were more likely to show increases in cyberbullying at wave 2 (two months later). These associations with positive reinforcement and positive attitudes were especially pronounced for the students from the US. The authors note that culture is a variable that is absent from longitudinal analyses on cyberbullying, yet, they do not discuss the implications of their findings. However, given that the study is described in terms of the effects of self-construals on aggression, the findings suggest that helping students adapt their construals from independent (i.e., mainly focused on self and autonomy) to interdependent (i.e., viewing self within the broader social context) may be one avenue for reducing cyberbullying involvement, especially among White youth in the US (Barlett et al., 2014). Taken together, these studies suggest that indeed, the impact of cyberbullying involvement and the factors that ameliorate or exacerbate associations may vary across groups.

Although some studies suggest that it is vital to consider cultural factors to identify distinct processes, there are also findings suggesting that some processes are universal. For example, in a study examining the relationship between proactive and reactive aggression with cyberbullying among adolescents from the US, (predominately White) and Singapore, the results showed no cultural differences (Ang, Huan, & Florell, 2014). Specifically, the authors found that both reactive and proactive aggression were related to cyberbullying in the US and

in Singapore. Thus, for some constructs relevant in cyberbullying involvement, the nature of online interactions may be similar cross-culturally.

Another way to examine the role of ethnicity and culture within cyberbullying research is by conducting studies among a single ethnic minority group to investigate within-group differences. Such within group differences include examination of developmental, gender or socio-economic status differences in cyberbullying involvement or the ways in which protective or risk factors function vary based on gender, for example. Few studies explore differences within one specific ethnic group or culture. One exception is a study by Låftman and colleagues (2013) who found that online victimization was related to poorer subjective health (e.g., headaches, poor appetite, problems falling sleep) more strongly among more recent immigrant adolescents in Sweden compared to adolescents who had lived in Sweden for more than 10 years (or their entire lives). In a study conducted with Latino youth in the US, Espinoza (2015) found no differences based on generational status, but the associations between daily experiences with cybervictimization (based on daily reports across five consecutive days) and feelings of distress and anger differed for boys and girls. Specifically, on any given day that girls reported being victimized online they also reported greater feelings of distress and anger on the same day. No such pattern was found for boys. Thus, these findings suggest that Latina girls are particularly at risk for emotional pain following a single incident of cybervictimization. Girls' greater sensitivity to online victimization has also been found in prior studies with ethnically diverse adolescents in the US (Bauman, Toomey, & Walker, 2013) and adolescents in Sweden (Låftman, Modin, & Östberg, 2013). Such findings are consistent with a larger body of research on social stressors: adolescent girls are typically more sensitive to social stressors and react more strongly to them (e.g., Wagner & Compas, 1990). Thus, studies that rely on one ethnic or cultural group can provide important insights about the nuanced ways in which youth react to cybervictimization.

As research on cyberbullying across the globe continues to grow, we will better comprehend the extent to which cyberbullying is a universal phenomenon and whether such online incidents are experienced differently across cultures. Extending many of the questions addressed in research conducted in the US, recent international studies have examined particular cyberbullying questions in different cultural contexts. For example, the ways in which cyberbullying is related to distress and self-esteem among students from Quebec schools showed that, over and above experiences of peer victimization in school, online victimization was related to more distress and lower self-esteem (Cénat, Hébert, Blais, Lavoie, Guerrier, & Derivois, 2014). These findings parallel studies conducted among adolescents in North America (e.g., Juvonen & Gross, 2008). International studies have also recently tested the link between online disinhibition and cyberbullying behaviors among high school students in Japan (Udris, 2014), whether associations exist between cyberbullying and anger among Italian youth (Lonigro, Schneider, Laghi, Baiocco, Pallini, & Brunner, *in press*), and relationships between cyberbullying and school-related happiness and life satisfaction among children in Spain (Navarro, Ruiz-Olivia, Larrañaga, & Yubero, 2015). These studies are beneficial because the more studies that are conducted on the topic make meta-analyses more feasible. A recent meta-analysis examined whether country of origin moderated relationships between cyberbullying involvement and numerous behavioral and psychological variables (Kowalski, Schroeder, Giumetti, & Lattanner, 2014).

The results revealed that cybervictimization was more strongly linked to higher feelings of loneliness and lower self-esteem among youth from North America than among European and

Australian youth (samples from youth in Asian countries were excluded due to the small number of studies). One explanation the authors offer is that there seem to be more nationwide intervention efforts taking place in European countries compared to in North America. Thus, the intervention effects may confound these apparent cultural differences.

RECOMMENDATIONS FOR FUTURE RESEARCH

Research aimed at providing a more comprehensive understanding of cyberbullying, its potentially negative consequences, and identification of relevant risk and protective factors is critical. It is important for future research to at least explore the role of ethnicity and culture as the body of knowledge on cyberbullying is increasing. Numerous studies on cyberbullying have not capitalized on the ethnic diversity of their sample by at least exploring such differences (e.g., Hinduja & Patchin, 2013; Williams & Guerra, 2007; Wright, *in press*). Research that both descriptively considers race, ethnicity and/or country of origin, and also research that highlights these factors as a key part of the study (e.g., testing moderation by ethnic background) can help us comprehend which findings are universally robust as opposed to more culturally nuanced. For example, we know relative little about socio-economic status (SES), and indeed need to make sure that ethnic differences are not confounded by SES.

Just as there is a void of research on lower SES youth, there are also other groups largely missing in research on cyberbullying conducted in North America. Only a handful of studies have included Asian youth in their sample (see Goebert, Else, Matsu, Chung-Do, & Chang, 2011). In the absence of studies of Asian youth, schools and school districts with Asian student populations are not in the position to address specific social-emotional needs of these students, inasmuch as cyberbullying is typically linked to higher levels of distress and depressive symptoms (e.g., Kowalski, Giumetti, Schroeder, & Lattanner, 2014). Even comparisons on mere rates of cyberbullying and victimization are relevant for intervention. At the same time, if studies continue to show that African-American youth are at greater risk of engaging in cyberbullying, the question might be whether any antibullying program can decrease their negative online behavior. Now that essentially all youth have online access, recognizing that adolescents' online and offline social worlds are increasingly interconnected is important (Reich, Subrahmanyam, & Espinoza, 2012). That is why we need to place research findings in their larger context by recognizing that aggression rates in general show a similar pattern of ethnic differences as do cyberbullying perpetration rates or that the mental health correlates of cybervictimization may be more severe among girls than boys given that girls, in general, are more sensitive to social stressors. It is also important to recognize that there are many challenges in conducting cross-cultural research. It is often difficult to ensure the same meaning of terms. That is, translating the words "bullying" and "cyberbullying" into other languages is at times challenging (Smith, del Barrio, & Tokunga, 2013). For example, in Japan, *ijime*, is the closest term for bullying and it is not an exact parallel as it focuses more on group processes, much like the term "mobbing" that was used in Scandinavian countries (Roland & Munthe, 1997). Thus, although it is easy to consider online communication as a universal phenomenon, it is important to consider the larger cultural context as well as the meaning of the terms used in cross-cultural research when assessing cyberbullying (Strohmeier, Aoyama, Gradinger, & Toda, 2013).

Given these potential limitations in cyberbullying research to execute cross-cultural studies, there has been a push to develop cross-culturally valid scales, although these efforts have been found to be quite challenging (e.g., Strohmeier, Aoyama, Gradinger, & Toda, 2013). Another strategy for avoiding conceptual confusion when conducting cross-cultural research on cyberbullying experiences is to ask about specific behaviors, a recommendation that has also been made for studying school bullying (Smith, Cowie, Olafsson, & Liefhoghe, 2002). One of the critical questions is whether there are good theoretical or conceptual reasons to expect electronic bullying to differ across ethnic and cultural groups. We expect that while the rates of the behavior may indeed parallel those documented for general aggressive behaviors, the rates of cybervictimization should not vary in any systematic way across specific ethnic or cultural groups, unless the behavior is motivated by (ethnic) prejudice, a topic that has also received little empirical attention (see Tynes, Giang, Williams, & Thompson, 2008). However, we do expect that there may be differences based on ethnic and cultural backgrounds in the extent to which certain factors serve a protective or risk-amplifying role for youth. As suggested by the current review, cultural differences have been found in the ways that online peer dynamics (e.g., reinforcement for bullying) function for cyberbullying perpetration (Barlett et al., 2014).

Similarly, there is evidence suggesting that the ways in which parental solicitation and monitoring function to curb online victimization might vary across ethnic groups (e.g., Shapka & Law, 2013). These types of research examples underscore the ethnic and cultural nuances of online behaviors and experiences.

Given that school context is relevant for cyberbullying experiences (e.g., Beale & Hall, 2007), and that many online victims report that they know their bullies from school (Juvonen & Gross, 2008; Kowalski & Limber, 2007), it may be important for cyberbullying studies to take into consideration the ethnic composition of adolescent's schools. School ethnic composition is relevant to students' feeling of safety within the context of school bullying incidents (e.g., Juvonen, Nishina, & Graham, 2006; Vervoort, Scholte, & Overbeek, 2010) and it may also be relevant for cybervictimization. Moreover, it would be important to understand whether cyberbullying takes place among same-ethnic peers as opposed to between racial or ethnic groups, especially since peer constructs such as social preference matter in cyberbullying perpetration (Wright, 2014).

While the content of online interactions (e.g., racial overtones) can be studied observationally in public domains (e.g., Twitter messages—see Bellmore, Calvin, Xu, & Zhu, 2015), the motivations for engaging in cyberbullying are more difficult to infer.

Recognizing and understanding the role of ethnicity and culture in cyberbullying involvement will become particularly important as efforts towards developing intervention and education programs on cyberbullying continue to grow. Can the same program that was piloted in London be then implemented in Canada? Can an intervention focused on increasing empathy and providing parent education as a means to decrease cyberbullying rates be successful if it is implemented across a school district in a large US city that has schools varying widely in students' ethnic composition?

In sum, adolescents' social worlds are increasingly taking place online, and cyberbullying is clearly an international phenomenon.

Accordingly, research that aims to better understand how ethnicity and race, as well as cultural values and belief systems across various countries influence or alter cyberbullying experiences is much needed.

INTRODUCTION

Cyberbullying can be defined as “willful and repeated harm inflicted through the use of computers, cell phones, and other electronic devices” (Hinduja & Patchin, 2009, p. 5). Studies have shown that cyberbullying victims and perpetrators have experienced mental health problems such as symptoms of depression (e.g., Bonanno & Hymel, 2013), suicidal ideation (e.g., Bonanno & Hymel, 2013; Hinduja & Patchin, 2010), and suicide attempts (e.g., Hinduja & Patchin, 2010). Even as the number of media reports of victims of cyberbullying who have committed suicide has increased, there is still a paucity of cyberbullying preventions and interventions that have been evaluated empirically (e.g., De Nies, Donaldson, & Netter, 2010; Friedman, 2010; Michels, 2008; Smith-Spark & Vandoorne, 2013). We review the prevalence of cyberbullying in the college student population and discuss various approaches that have been taken to deliver preventions and interventions to reduce cyberbullying perpetration among youth and college students. Next, cyberbullying bystander and victim research will be discussed. Then, we propose future directions and ways in which cyberbullying preventions and interventions can become more comprehensive and effective.

CYBERBULLYING PREVALENCE

The vast majority of studies on cyberbullying have been targeted toward youth (Tokunaga, 2010). Given the fact that children and young adolescents are moving through a developmentally critical time in which cyberbullying tends to peak (e.g., Beran & Li, 2005; Patchin & Hinduja, 2006; Salmivalli, Kärnä, & Poskiparta, 2011), specific attention to this developmental period is clearly warranted. However, prevalence of cyberbullying among college students is also high and the consequences can be just as severe as those experienced by younger populations. Prevalence rates of being cyberbullied vary drastically based on how cyberbullying is conceptualized, measured, and the samples utilized (e.g., 9% to 55%; Aricak, 2009; Dilmaç, 2009; Kraft & Wang, 2010; MacDonald & Roberts-Pittman, 2010; Schenk & Fremouw, 2012; Walker, Sockman, & Koehn, 2011). Our research group has developed and validated with college students arguably the most comprehensive assessment of both cyberbullying victimization and cyber perpetration, the Cyberbullying Experiences Survey (CES; Doane, Kelley, Chiang, & Padilla, 2013), which includes 21 victimization and 20 perpetration behaviors that reflect four distinct types of cyberbullying: deception, malice, public humiliation, and unwanted contact. Using this broad assessment of cyberbullying occurring in the past year, approximately 78% of college students reported experiencing and 53% reported perpetrating at least one form of cyberbullying involving deception, 88% reported experiencing and 78% reported perpetrating cyberbullying involving malice, 73% reported experiencing and 38% reported perpetrating cyberbullying involving public humiliation, and 66% reported experiencing and 29% reported perpetrating cyberbullying involving unwanted contact. According to these estimates, the vast majority of college students have been both a victim and a perpetrator of cyberbullying behaviors in the past year.

CHANGE THE BULLY

In recent years, several cyberbullying prevention programs developed for youth in many different countries have demonstrated effectiveness for increasing knowledge of cyberbullying, improving strategies for stopping cyberbullying, and reducing cyberbullying behavior. With few exceptions, these programs have been designed for youth between the ages of 11 and 14 (e.g., Lee, Zi-Pei, Svanström, & Dalal, 2013; Salmivalli et al., 2011); however, Wölfer et al. (2014) included youth up to age 17 and Menesini, Nocentini, and Palladino (2012) included secondary students ranging from 14 to 20 years old (mean age = 16.29). One of the most notable limitations to current cyberbullying research is that not all cyberbullying prevention programs have incorporated a theoretical framework (Tokunaga, 2010). Given the heterogeneity in cyberbullying perpetration and victimization, one theory may not account for all types of cyberbullying perpetration and cyber victimization. Nevertheless, without strong theoretical frameworks to guide research, any prevention and intervention attempts may be misinformed. With this caveat in mind, in this section, we review the results of several recent cyberbullying programs designed for school-aged children and our own cyberbullying work with college students. In a study testing the effectiveness of a cyberbullying prevention program (i.e., Media Heroes) for German adolescents, Wölfer and colleagues (2014) utilized the Theory of Planned Behavior (TPB; Ajzen, 2012) which is a more recent, expanded version of the Theory of

Reasoned Action (TRA; Fishbein & Ajzen, 1975). TRA was first introduced in 1969 by Ajzen and Fishbein to identify antecedents to various behaviors. TRA posits that attitudes toward a behavior (i.e., the degree to which a behavior is positively or negatively evaluated) and perceived norms [perception of others' approval or disapproval of performing a behavior (injunctive norms) or the perception that others actually engage in the behavior (descriptive norms)] influence behavioral intentions (Fishbein & Ajzen, 2010). Behavioral intentions are proposed to have a direct effect on the behavior itself. In addition to TRA constructs (i.e., attitudes and perceived norms), TPB includes perceived behavioral control (i.e., the degree to which individuals believe that one can successfully execute the behavior) as a predictor of behavioral intentions (Ajzen, 2012).

Wölfer et al. (2014) developed a program (i.e., Media Heroes) that is based on several developmental and psychological constructs that also reflected some basic TPB core constructs. In a test of the Media Heroes program, students between the ages of 11 to 17 participated in 10 weekly 90-minute sessions (long intervention) or 4 90-minute sessions on a single day (short intervention). Media Heroes incorporates teaching the definition and legal rights associated with cyberbullying and increasing perspective-taking and empathy, changing existing norms regarding social responsibility, and increasing students' behavioral control such as online protective behaviors and strategies to confront cyberbullying. A number of teaching techniques are utilized including role playing, peer tutors, student-to-parent teaching, and reflection. Both the long and short intervention programs decreased cyberbullying behavior, increased perspective-taking skills and reduced non-cyberbullying specific instrumental and reactive aggressive behavior at nine months post-test compared to a control group; the short and long intervention groups did not differ significantly from one another.

Based on social constructivism, scaffolding theory, and collaborative learning theory, Lee and colleagues (2013) developed a student-administered, web-based, exploratory-oriented, eight-session cyberbullying prevention course (i.e., 360 minutes that took part over the course of four consecutive weeks) for Taiwanese students. The program targets student knowledge and attitudes toward cyberbullying as well as reduction in cyberbullying behavior. Although the program did not improve students' attitudes toward cyberbullying, as compared to those in the control group, those who took part in the web-based cyberbullying prevention program demonstrated greater knowledge of cyberbullying and reduced intentions to cyberbully immediately following program completion and two weeks after the conclusion of the program. Benefits of the Lee et al. program include the ability of students to problem solve and complete tasks by interacting with peers online and that the program can be completed by students themselves. The KiVa Antibullying Program (KiVa), developed by a team of Finnish researchers (Salmivalli et al., 2011), focuses on enhancing empathy, self-efficacy, and antibullying attitudes of bystanders. KiVa, a 20-hour program, is delivered in two 1-hour classroom lessons per month for elementary school children or four times during the school year for middle school children. KiVa instruction focuses on the complex dynamics of bullying and cyberbullying, including bystander roles. It includes step-by-step instruction for the curriculum lessons which are delivered by trained teachers. Furthermore, KiVa incorporates a parent guide which contains information on what parents can do about bullying/cyberbullying (Salmivalli & Poskiparta, 2012). In a test of the program for Finnish youth in grades 4 through 9, as compared to students in the control condition, students who took part in KiVa reported reduced cyberbullying victimization at posttest (Williford et al., 2014). The effect of the program on cyberbullying perpetration, however, was conditional based on student age.

Specifically, the program was effective for students who were one standard deviation below the mean age (i.e., 11.30 years) but not effective for students at (i.e., 12.88 years) or above (i.e., 14.46 years) the mean participant age. Importantly, the researchers also found classroom effects such that cyberbullying perpetration and victimization were more common in some classrooms.

In two studies, Menesini et al. (2012) evaluated the effects of the “*Noncadiamointrappola*” program (translated: “*Let’s Not Fall into a Trap*”) designed to reduce bullying and cyberbullying in secondary schools in Italy. Based on the longstanding view that peers learn from liked and trusted group members [i.e., a peer education model (e.g., Turner & Shepherd, 1999)], Study 1 compared students who were highly involved (i.e., took part in training and worked on an activity in a real or virtual community; $n = 63$) to students who received an intervention based on raising awareness of cyberbullying ($n = 126$) to those in the control group ($n = 47$). A significant reduction in cyberbullying was shown only for those who served as peer educators, particularly for male peer educators. Study 2 included stronger attention to the victim’s role and support for victims, greater effort to involve bystanders, face-to-face instruction by peer educators which was supported by classroom teachers that included a short movie on cyberbullying and guide for safer e-mail and social network use, and the creation of a Facebook group where online peer educators posted links and served as group administrators. Results of Study 2 revealed a significant Time by Group effect such that traditional bullying perpetration, bullying victimization, and cyberbullying victimization, but not cyberbullying perpetration, decreased for students who took part in the experimental as compared to the control group. Collectively, these studies show the importance of more extensive involvement as opposed to global information regarding cyberbullying and that peer educators can serve as instruments of change in promoting reduction of cyberbullying victimization among their peers.

Based on the idea that traditional bullying and cyberbullying have overlapping risk and protective factors, Gradingier, Yanagida, Strohmeier, and Spiel (2015) tested whether a general antibullying program would have benefits on cyberbullying among Austrian children grades 5 to 7. In the first semester of the two-semester program, teachers receive training on school level intervention and prevention. In the second semester, teachers provided 13 lessons that cover bullying prevention and instruct students on working together to reduce classroom bullying. Importantly, students carry out a class project with the intention of creating an encouraging, structured, and friendly environment in which it is believed bullying is less likely to occur. Results of a longitudinal randomized control group design revealed that the program reduced both cyberbullying perpetration ($d = 0.39$) and cyberbullying victimization ($d = 0.29$); however, some differences were noted in program effectiveness depending on age, gender, and pre-test cyberbullying perpetration and victimization. Specifically, higher cyberbullying perpetration at pretest was associated with decreases in cyberbullying perpetration in the control and intervention group. Girls showed a stronger decrease in cyberbullying perpetration than boys in the intervention group; as compared to younger students, older students showed a stronger increase in cyberbullying perpetration. The mean change in cyberbullying victimization was related to pretest cyberbullying victimization and gender. Higher cyberbullying victimization at pre-test was associated with greater decline in cyberbullying victimization in both the control and intervention groups, and girls showed a greater decline in cyberbullying victimization in the intervention group compared to boys.

Led by researchers at four Australian universities (i.e., Barbara Spears, Phillip Slee, Marilyn Campbell, and Donna Cross) in 2010, the Australian Universities’ Anti-bullying Research Alliance (AUARA) was formed. From this initiative, four independent programs of

research were developed to address youth cyberbullying perpetration and cyberbullying victimization. The “*Keep it Tame*” program is an antibullying, social marketing campaign co-created by youth, marketing, and research experts (Spears & Zeederberg, 2013). The *Cyber Friendly School Project* (Cross et al., 2003) engages students, teachers, parents, and the community and focuses on providing students with information and skills to increase empathy toward victims, cope with cyberbullying, and to react assertively and non-aggressively to cyberbullying. Led by Marilyn Campbell at Queensland University of Technology, an additional two-fold program has been designed to examine the knowledge and attitudes of the school community to legal responses for cyberbullying and to develop and test legally-informed resources to these findings (see Cross, Campbell, Slee, Spears, & Barnes, 2013 for a discussion). Finally, a fourth program, developed at Flinders University, provides teacher training and shows students a DVD (i.e., *Coping with Bullying*; Slee, Murray-Harvey, & Wotherspoon, 2008), which includes scenes of online bullying and focuses on coping strategies depending on a mix of personal and situational variables. While results of these programs are preliminary, current evaluations of these programs have been positive (see Cross et al., 2013). Our work has utilized the TRA (Fishbein & Ajzen, 1975) as a framework for understanding cyberbullying perpetration among college students (Doane, Kelley, & Pearson, in press; Doane, Pearson, & Kelley, 2014, 2015). Studies measuring empathy in general (Schultze-Krumbholz & Scheithauer, 2009) and empathy specifically related to cyberbullying (Steffgen, König, Pfetsch, & Melzer, 2011) have found higher levels of empathy to be associated with lower levels of cyberbullying. For this reason, we included empathy as a distal antecedent to cyberbullying.

Prior to a series of studies examining the utility of TRA (Ajzen, 1985) for understanding college student cyberbullying behavior, we developed the four-factor Cyberbullying Experiences Scale to assess past-year experiences with cyberbullying (CES; Doane, Kelley, Chiang, & Padilla, 2013). The CES assesses four dimensions (i.e., malice, public humiliation, unwanted contact, and deception) of cyberbullying perpetration and victimization. Importantly, the CES allows for tests of TRA constructs on different classes of cyberbullying behaviors common among emerging adults (i.e., 18 to 25; Arnett, 2000).

In our first application of TRA as an explanatory framework for cyberbullying behavior among college students (Doane et al., 2014), we extended earlier work by Heirman and Walrave (2012) conducted with Belgian adolescents. Using the TPB (Ajzen, 2012), Heirman and Walrave found that attitudes, subjective norms, and perceived behavioral control predicted cyberbullying intentions, which in turn predicted cyberbullying behaviors. Although TPB includes perceived behavioral control, because our research focuses on college students, 98% of college students use the Internet (Pew Internet & American Life Project, 2013), and 97% of individuals in our targeted age range use their phone for texting (Duggan & Rainie, 2012), college students have the ability to execute cyberbullying behaviors; thus, we believed TRA model was more appropriate for our work. Importantly, we matched each attitude, injunctive norm, and descriptive norm to each cyberbullying behavior item.

More specifically, our intent was to examine the degree to which attitudes toward cyberbullying, injunctive norms, and descriptive norms predicated cyberbullying intentions, which were expected to predict cyberbullying behaviors. In addition, we hypothesized that empathy toward cyberbullying victims on cyberbullying intentions would be mediated by the TRA constructs (i.e., attitudes toward cyberbullying, injunctive norms, and descriptive norms).

Using path analyses, Doane et al. (2014) tested the TRA model across all four types of cyberbullying (i.e., malice, public humiliation, unwanted contact, and deception). The TRA-based model accounted for a substantial portion of variance in cyberbullying intentions and cyberbullying behavior (see Figure 1). As expected from previous research (e.g., Heirman & Walrave, 2012), attitudes toward cyberbullying was the best predictor of all four forms of cyberbullying intentions examined. Furthermore, empathy toward cyberbullying victims had indirect effects on cyberbullying behaviors through TRA constructs.

Although several recent cyberbullying prevention programs have been developed for youth, few such programs are available for emerging adults. Building on our earlier work and guided by the TRA, we developed a video-based program for college students designed to increase cyberbullying knowledge and empathy toward cyberbullying victims, decrease favorable attitudes regarding cyberbullying, diminish positive injunctive and descriptive norms about cyberbullying, and decrease intentions to cyberbully and cyberbullying behaviors (Doane et al., in press). The content of the video was developed from a review of the literature, an interview study with 43 college students who indicated they have been the target of cyberbullying (Doane, Kelley, & Cornell, 2009), and content experts. From these sources, scripts were developed, which were then reviewed by a cyberbullying expert not associated with the research, faculty members, and graduate students. The scripts were then refined and piloted.

Figure 1. Summarizes the results from four fully saturated models for each type of cyberbullying behavior: Deception, Malice, Public Humiliation (Pub Hum), and Unwanted Contact (Unw Cont). Attitudes, injunctive norms, and descriptive norms were significantly positively correlated with each other across all 4 models; demographic covariates (age and gender) were modeled as predictors of all other variables in the model; these paths are not shown for reasons of parsimony.

Once the scripts were finalized, student actors were recruited and supervised, and the video was filmed and edited. The video was comprised of six brief cyberbullying scenarios enacted by the actors. The common cyberbullying events were interspersed with brief attention-grabbing slides with voiceovers regarding well-publicized cyberbullying events involving

adolescents and emerging adults as well as short, key information regarding cyberbullying. To generate empathy toward cyberbullying victims, the scenarios illustrated how upsetting cyberbullying can be to victims (e.g., a student in her dorm room receiving constant hurtful instant messages). To target decreasing positive injunctive and descriptive norms, various actors discussed and commented on how “immature” and “stupid” cyberbullying was as well as on how other students may perceive cyberbullying as wrong. In one scenario, a student confronted a cyberbully when he asked her to assist him and explained why she intervened. Results of a randomized pre-test, post-test, 1-month follow-up design revealed that compared to pre-test, those in the video prevention condition reported immediate benefits for attitudes and injunctive norms for all four forms of cyberbullying behaviors examined. In addition, the video prevention decreased descriptive norms of selected forms of cyberbullying (i.e., malice and public humiliation), increased empathy for victims of selected forms of cyberbullying (i.e., malice and deception), and increased cyberbullying knowledge. At the one-month follow-up, malice and public humiliation behaviors, favorable attitudes toward unwanted contact, deception, and public humiliation, and injunctive norms for public humiliation were significantly lower for the experimental group relative to the control condition. Thus, results suggest a brief cyberbullying video may have short-term benefits for cyberbullying knowledge, constructs associated with cyberbullying (e.g., injunctive norm, descriptive norms, and empathy toward cyberbullying victims), and cyberbullying behavior.

More recently, Doane et al. (2015) tested the efficacy of an in-person video-based cyberbullying prevention program [using the same video as Doane et al. (in press)] and a student-led, skit-based prevention program for the reduction of cyberbullying behavior. Both programs were developed to test TRA. In Study 1, we examined the efficacy of an in-person cyberbullying video prevention program with 335 college students. Immediately after the program ended, attitudes toward and injunctive norms for all four types of cyberbullying (i.e., malice, deception, unwanted contact behaviors, and public humiliation), intentions to engage in malice, willingness to engage in malice and deceptive behaviors, and empathy toward victims of all four forms of cyberbullying significantly improved. Also, subjects reported less malice, deception, and public humiliation perpetration at one-month follow-up. In Study 2, the theory-based prevention program was tested using a pre-post design via student enacted skits that depicted several cyberbullying scenarios. Students also presented information about cyberbullying. Attitudes and injunctive norms toward malice, deception, and public humiliation behaviors as well as intentions and willingness to engage in malice behaviors decreased. Furthermore, knowledge of cyberbullying increased from pre- to post-test.

CHANGE THE BYSTANDER

Although most cyberbullying research has focused on victimization and perpetration, recent studies have begun to address the role of bystanders (i.e., witnesses of cyberbullying) in the context of cyberbullying (e.g., DeSmet et al., 2014; Van Cleemput, Vandebosch, & Pabian, 2014). Some cyberbullying prevention and intervention programs have targeted changing norms and/or addressed bystander behavior with the purpose of reducing cyberbullying perpetration and/or victimization (e.g., Doane et al., in press; Doane et al., 2015; Menesini et al., 2012; Williford et al., 2014). However, no published cyberbullying programs, to our

knowledge, have tested for changes in bystander behavior. Nonetheless, some programs that have addressed bystander behavior have been successful in reducing cyberbullying victimization (e.g., Menesini et al., 2012; Williford et al., 2014) and perpetration (e.g., Doane et al., in press; Doane et al., 2015; Williford et al., 2014). Thus, the bystander role should be further examined in tests of cyberbullying prevention and intervention programs. Due to the lack of research on cyberbullying bystander prevention programs, this section will review studies on cyberbullying bystanders more generally, including its prevalence and predictors, and conclude with future directions for changing cyberbullying bystander behavior.

As with cyberbullying victimization and perpetration, the prevalence rates of cyberbullying bystander behavior have also varied, due in part to differences in methodology (e.g., responses to scenarios, self-reported past behaviors, age, modes of communication, time window of assessment). Based on self-reports, the percentages of individuals who have witnessed cyberbullying have ranged from approximately 28% to 57% (Li, 2010; Van Cleemput et al., 2014; Vandebosch & Van Cleemput, 2009; Whittaker & Kowalski, 2015). Two studies examined the types of cyberbullying incidents participants witnessed. In a sample of 837 students grades 5 to 12 in Taiwan, Yang, Lin, and Chen (2014) found that the most common types of cyberbullying students witnessed were “ignoring posting” (36.0%), “instigating friends to exclude someone” (33.2%), and “mocking or making fun using sexually discriminatory wording” (32.3%). Based on Belgium youths’ reports, Vandebosch and Van Cleemput (2009) found that the most common cyberbullying behaviors witnessed were “deception, pretending to be someone else” (50.9%), “making threats or insults by email or mobile phone” (49.3%), and “spreading of gossip by email or mobile phone” (41.1%).

Several studies have examined specific self-reported bystander reactions. For example, in a qualitative study of Canadian students in grades 7 to 12, most students (70.2%) viewed the cyberbullying without joining, and more than one-fourth removed themselves from the situation (Li, 2010). Fewer students participated in the cyberbullying (13.3%) or encouraged the bully (12.6%). About one-third (35.1%) attempted to support the victim and 23.2% indicated they confronted the bully directly. Only 9.3% reported the event, and 8.6% protested to individuals other than the bully. In a recent study of Flemish adolescents ages 9 to 16, only 4.6% reported assisting the perpetrator, 45.1% reported assisting the victim, and 58.6% did nothing (Van Cleemput et al., 2014). The three most common explanations for doing nothing were “because it is not my business,” “because I could get bullied myself,” and “because I did not know how to help the victim.” In a younger sample of Swedish students grades four to nine, Slonje, Smith, and Frisén (2012) found that of the 149 students who were identified as bystanders, most (72%) did not pass on the cyberbullying information, 13% attempted to help the victim by informing the victim of the incident, 9% passed the information to friends, and 6% attempted to extend the bullying by showing the victim the information. In the US, Freis and Gurung (2012) measured the reactions of 37 undergraduate women ages 18 to 23 to a scripted Facebook discussion with confederates who bullied someone based on sexual orientation. The majority of the participants (90.6%) intervened, of which most confronted the bully, about half changed the topic of conversation, and fewer tried to comfort the victim or made direct comments. Across these studies of self-reported bystander behavior, it was found that the majority of cyberbullying bystanders do nothing. Although fewer participants responded to cyberbullying incidents, of those who did react, more reported helping the victim than assisting the bully.

Given that most individuals do not respond when witnessing cyberbullying incidents, the identification of cyberbullying bystander predictors is essential to inform prevention and intervention efforts. Cyberbullying studies have examined both individual characteristics of bystanders and contextual predictors of bystander behavior. However, measures of bystander behaviors have varied, including qualitative (e.g., DeSmet et al., 2014), self-reported bystander behavior (e.g., Macháčková, Dedkova, Sevcikova, & Cerna, 2013), and manipulated scenarios and situations (e.g., weight-based Facebook comments on a photo, Anderson, Bresnahan, & Musatics, 2014; altered picture of a boy, Barlińska, Szuster, & Winiewski, 2013; insulting comment versus photo of person using the bathroom on Facebook, Bastiaensens et al., 2014; same-gender hypothetical blog scenario written by victim describing a fake Facebook page that was made up about him/her, Holfeld, 2014).

In focus groups of 61 adolescents in Belgium, DeSmet et al. (2014) found that bystander behavior depends on the context. For instance, adolescents reported being more likely to tell an adult when the bullying was repeated or severe (i.e., physical threats), and that those who have more social support (e.g., being popular) were more likely to confront the bully. In addition, adolescents considered peers who reinforce the bullies' behavior as "fake friends or trying to fit in" and defenders as "popular" or "strong" (p. 209-210). However, friends doing nothing was considered acceptable, as adolescents believed that their peers would expect bystanders to comfort the victim but not confront the bully. "Loners" (i.e., those who behave "differently," p. 210) were blamed for being victims and were viewed as not deserving to be defended by bystanders.

In a self-report study of bystander behavior among Czech youth ages 12 to 18, Macháčková et al. (2013) found that having a good relationship with the perpetrator was related to being less likely to support the victim (e.g., offering advice or comfort). In contrast, participants higher on prosocial behavior, having a relationship to the victim, feeling upset about seeing the incident (the strongest predictor), and the victim asking for help predicted high levels of support toward the victim. Self-esteem and peer rejection did not predict supportive behavior.

Studies employing cyberbullying scenarios have examined a variety of bystander predictors. In a study of US college students, Anderson et al. (2014) manipulated others' weight-based comments on a Facebook photo in three conditions: dissenting (i.e., among negative weight-based comments, some comments were supportive of the victim or against the bully), conformity (i.e., all negative comments), and no comments. Students who viewed dissenting comments made more positive comments than participants in the conformity or no comments groups. Dissenter effects were stronger for men such that men in the dissenting condition made the most positive comments and were least likely to rate the victim as unhealthy. In addition, Barlińska et al. (2013) found that Polish students (ages 11-18 years) were more likely to select negative bystander responses (e.g., "forward to a peer," "put it up in the school's hall," p. 42) in online and private contexts compared with face-to-face and public contexts. In a study of Flemish adolescents, when manipulating contextual factors (i.e., severity, others reinforce the bully or defend the victim, relationship to other bystanders) in Facebook scenarios, Bastiaensens et al. (2014) found that intentions to help the victim were higher in the more severe scenario (i.e., private photo posted) than the less severe scenario (i.e., insulting comment). In the less severe situation, participants reported higher intentions to comfort and give advice to the victim when the other bystanders were acquaintances than when the others were good friends. On the other hand, participants had higher intentions to comfort and give advice to the victim in the more severe situation when the other bystanders were their

good friends than when the other bystanders were their acquaintances. Participants had higher intentions to reinforce the bully when the other bystanders engaged in behavior similar to the bully and were their good friends compared to when the bystanders were their acquaintances. However, when the other bystanders defended the victim, participants reported lower intentions to reinforce the bully when the other bystanders were their good friends than when they were their acquaintances. In sum, bystander responses to scenarios have varied as a function of several factors including individual characteristics and the context.

Multiple studies have examined empathy in the context of bystander behavior. Anderson et al. (2014) found no differences in empathy toward the victim between the dissenting conditions (dissenting, conforming, and no comments). Barlińska et al. (2013) attempted to activate affective empathy in one study by showing a two-minute video illustrating the effects on and feelings of a victim and cognitive empathy in another study by showing the same video but asking participants to focus on a) the victim's emotions, b) the victim's behavior, or c) the background. They found that affective and both types of cognitive empathy activation resulted in a lower likelihood of selecting a hypothetical negative bystander response (i.e., forwarding a message) compared with the control groups. In Van Cleemput et al.'s (2014) study, empathetic concern was a significant predictor of previous bystander behavior, such that higher levels of empathy were associated with helping the victim and lower empathy levels were related to doing nothing and helping the bully. Similarly, college students who were high in extraversion, empathy, and favorable attitudes toward homosexual individuals were more likely to intervene in the sexual orientation bullying scenario (Freis & Gurung, 2012). Thus, across most of these studies, higher levels of empathy were associated with positive bystander behaviors. However, more studies examining the relationship between empathy and bystander behavior are necessary.

In addition to empathy, gender and age have been common variables in cyberbullying bystander research. For instance, Yang et al. (2014) found that boys and older students were more likely to have witnessed cyberbullying than girls and younger students. In addition, Bastiaenssens et al. (2014) found that compared to boys, girls had higher intentions of helping the victim by giving advice, providing comfort, and defending the victim. However, boys reported higher intentions than girls to tell the perpetrator that the incident was funny. Among middle school students, Holfeld (2014) found that boys held the victim more responsible and placed more blame on the victim for the cyberbullying incident than girls. In the Van Cleemput et al. (2014) study, although gender did not predict previous bystander behavior, older adolescents were more likely to join the bully or do nothing and less likely to help the victim. In a study of Portuguese students ages 10 to 18, older students and boys had more negative attitudes toward defenders (Almeida, Correia, & Marinho, 2010). Although more research is needed, based on these studies, older youth and boys may need cyberbullying bystander prevention and intervention programs more than younger youth and girls.

CHANGE THE VICTIM

It is important to note that nearly anyone using electronic communication can experience cyberbullying victimization. Thus, we must be careful not to blame the victim. It is important, however, to understand factors related to increased likelihood of being the victim of

cyberbullying so that prevention programs integrate this information. Although some broad bullying programs reviewed above showed reduction in cyberbullying victimization (e.g., Gradinger et al., 2015; Menesini et al., 2012; Williford et al., 2014), in this section, we summarize work on the characteristics and behaviors that place individuals at increased risk of cyberbullying victimization and targeted programs to reduce this risk.

Several studies with early to late adolescents have found that frequency of Internet use is positively related to cyberbullying victimization (Erdur-Baker, 2010; Helweg-Larsen, Schütt, & Larsen, 2011; Mesch, 2009; Mishna, Khoury-Kassabri, Gadall, & Daciuk, 2012; Mitchell, Wolak, & Finkelhor, 2008; Navarro & Jasinski, 2012; Vandebosch & Cleemput, 2009). In a sample of college students, Lindsay and Krysik (2012) found that social networking frequency was associated with increased 'online harassment' by someone known to the participant. Rather than simply pointing to the fact that increased exposure to electronic forms of communication places individuals at increased risk of cyberbullying victimization, it is important to examine specific behaviors that individuals engage in that place them at increased risk of cyberbullying victimization.

Although there is a degree of inconsistency across studies in terms of specific risky electronic communication behaviors that have been examined and their predictive validity, several specific risky electronic communication behaviors have been identified as predictors of cyberbullying victimization. These behaviors include agreeing to meet or inviting someone met online to meet in person (e.g., Mitchell et al., 2008), sharing personal information (e.g., Mesch, 2009), sharing passwords (e.g., Mishna et al., 2012), communicating with people known only online (e.g., Helweg-Larsen et al., 2011; Vandebosch et al., 2009), and using specific media (i.e., social networking websites, video sharing websites, and chatrooms; e.g., Mesch, 2009; Navarro & Jasinski, 2012).

The converse of risky electronic communication behaviors, or safety electronic communication behaviors, have been promoted as ways to reduce cyberbullying victimization. For example, Parris, Varjas, Meyers, and Cutts (2012) interviewed 20 high school students about their recommendations regarding protective strategies against cyberbullying. Twelve students (60%) suggested discussing interpersonal matters in person to avoid miscommunications that may lead to cyberbullying. All of the students recommended increased use of security strategies and awareness of Internet safety, such as not sharing passwords, frequently changing passwords, setting social networking profiles to private, not accepting friend requests from people with no mutual friends, being respectful of others, and being aware of cyberbullying in general.

Although some interventions designed to reduce cyberbullying victimization by targeting the victim have been attempted among youth, they have limited efficacy. As reviewed by Mishna, Cook, Saini, Wu, and MacFadden (2011), these psychoeducational Internet safety interventions for youth were somewhat associated with increasing Internet safety knowledge (Chibnall, Wallace, Leicht, & Lunghofer, 2006), but not effective at changing risky online behaviors (Chibnall et al., 2006; Crombie & Trinneer, 2003; Salvatore, 2006). Given the limited efficacy of these interventions, an important next step for prevention and intervention work is to understand the antecedents to risky (or safety) electronic communication behaviors. In a sample of adolescents in Singapore (ages 12-19), Lwin, Li, and Ang (2012) examined motivations behind intentions to adopt 'online safety behaviors' based on Protection Motivation Theory (PMT; Rogers, 1975, 1983). PMT posits that threat appraisal (i.e., perceived severity and perceived susceptibility) and coping appraisal (i.e., response efficacy and self-

efficacy) are cognitive processes aroused when one is confronted with a threat, which in turn are related to engagement in behaviors aimed to reduce the threat. Lwin et al. found support for PMT as perceived severity of cyberbullying, response efficacy, and self-efficacy (but not perceived susceptibility) regarding online safety behaviors were significant predictors of online safety behavioral intentions. In a sample of college students, Doane, Boothe, Pearson, and Kelley (2015) demonstrated that PMT variables were predictive of both risky electronic communication behaviors and cyberbullying victimization. These studies suggest the promise of PMT variables in mobilizing safe or reducing risky electronic communication behaviors in adolescent and young adult populations.

Like PMT, the Extended Parallel Process Model (EPPM; Witte, 1992) is another theoretical approach that focuses on perceived severity, perceived susceptibility, response efficacy, and self-efficacy as key mechanisms through which individuals respond to fear-based appeals. Guided by the EPPM, Roberto, Eden, Savage, Ramos-Salazar, and Deiss (2014) tested the effectiveness of the Arizona Attorney General's 45-minute Social Networking Safety Promotion and Cyberbullying Prevention presentation for middle school children. Approximately two-thirds of the presentation is focused on social networking safety, and one-third is focused on cyberbullying prevention. The key goals of the program were to change perceived severity, perceived susceptibility, response efficacy, self-efficacy, attitudes, and safe social networking behavioral intentions (e.g., not friending strangers, not posting photos, not meeting face-to-face). Two weeks prior to the presentation, the presenter sent a 'friend' request to student participants who were members of the middle school's Facebook page. The presenter began the presentation with information on the number of students who 'friended' the presenter and showed students the amount of personal information they were able to get from student's profile pages as well as how they were able to use this information in tandem with other information (e.g., Google maps) to increase student vulnerability. Compared to the control condition, those who took part in the program reported higher perceived severity, response efficacy, and safer social networking behavioral intentions. Unfortunately, the design did not permit an examination of actual changes in these behaviors and/or whether these changes decreased the incidence of cyberbullying victimization.

Overall, there is some evidence that prevention and intervention approaches based on a sound theoretical framework have promise for decreasing risky electronic communication behaviors. However, the endpoint in these studies was the risky and protective behavioral intentions or behaviors themselves, rather than cyberbullying victimization, which is an assumed consequence of these risky and protective electronic communication behaviors. Additional research is sorely needed that comprehensively examines cyberbullying victimization as the outcome, and continued examination of potential mediators or mechanisms through which such prevention/intervention approaches result in such differences is critical to tailoring and optimizing the effectiveness of these programs.

SUGGESTIONS FOR FUTURE RESEARCH

We strongly believe that the most promising interventions will be rooted in sound theory. One underdeveloped area in cyberbullying research is understanding the most salient antecedents to cyberbullying perpetration, bystander behavior, and cyber victimization. It is

imperative that we rigorously test distinct predictive models against each other to determine which models have the most predictive utility. We have reviewed studies above examining the Theory of Reasoned Action, Theory of Planned Behavior, Protection Motivation Theory, and the Extended Parallel Process Model. Although each of these models has some support, other theoretical models may be important. For instance, to explain and organize the factors identified in their meta-analysis of cyberbullying perpetration and victimization, Kowalski, Giumetti, Schroeder, and Lattaner (2014) discussed the general aggression model (GAM; Anderson & Bushman, 2002) as it applies to cyberbullying. GAM is a comprehensive theory of general aggression in which the effects of personality and situational variables are expected to be mediated by cognition, affect, and arousal. As described so aptly throughout this book, Bronfenbrenner's Ecological Systems Theory (Bronfenbrenner, 1999) reminds us that individual development does not occur in a vacuum; rather, individuals develop while being nested into specific contexts that range from microsystems to macrosystems. Thus, cyberbullying occurs to individuals who are nested within specific home, family, and peer environments as well as more "macro" level school systems, communities, and cultures; thus, it may be important to understand how these different systems interact to promote or prevent cyberbullying. A broader application of models currently being utilized and other models could enhance the theoretical basis of cyberbullying interventions and hopefully improve overall efficacy.

In addition to a need for theory-based cyberbullying programs, intervention and prevention efforts that target all cyberbullying roles (i.e., victims, perpetrators, and bystanders) are needed. Cyberbullying victim, perpetrator, and bystander roles have been found to be significantly related (e.g., Vandebosch & Van Cleemput, 2009; Yang et al., 2014). Across three studies, Barlińska et al. (2013) found previous engagement in cyberbullying perpetration predicted negative bystander responses. When examining previous traditional bullying or cyberbullying behavior as predictors of cyberbullying bystander behavior, Van Cleemput et al. (2014) found that previous victimization experiences for both forms of bullying predicted higher levels of helping behavior; previous traditional bullying victimization experiences predicted a lower likelihood of doing nothing. The title of our chapter poses a question regarding whether we ought to change the bully, change the bystander, or change the victim. Given the significant overlap in cyberbullying victimization, perpetration, and bystander behavior, it is important for prevention and intervention programs to target these three roles collectively. In doing so, evaluation of these programs requires comprehensive assessment of change in behaviors related to each of these roles. Thus, our review leads us to the conclusion that cyberbullying prevention/intervention can best be improved by focusing on the big picture: changing the bullies, changing the bystanders, *and* changing the victims.

Chapter 20

CYBERBULLYING REQUIRES MORE THAN A VIRTUAL RESPONSE: SUGGESTIONS FOR PREVENTION

INTRODUCTION

The dynamic between bully and victim has been a staple of coming-of-age films for decades—from Biff in *Back to the Future* (1985) to Regina in *Mean Girls* (2004)—each generation of films immortalizes this iconic relationship. This relationship continues to captivate filmgoers because it's so relatable; the bully-victim dynamic continues to be a ubiquitous part of the social fabric of schools, even as the methods of bullying have changed with the times. Although depictions of bullying are present in literature dating back to ancient Greece (e.g., Creon in Sophocles' *Antigone*), research on bullying did not begin in the United States until the 1990's (Berger, 2007).

THE RELATIONSHIP BETWEEN FACE-TO-FACE BULLYING AND CYBERBULLYING

Traditionally, there are three characteristics that distinguish bullying from other forms of aggressive behavior among peers. To be considered bullying, there must be: (1) Intent; the perpetrator must intend to cause harm to the victim, (2) Chronicity; the behavior must be repeated and chronic in nature, and a (3) Power differential; there must be some difference of power between the victim and the perpetrator (Solberg & Olweus, 2003). This general definition of bullying covers a broad spectrum of aggressive behaviors, which may be primarily

* Corresponding Author's Email: vswingate@gmail.com.

verbal, relational, physical, or any combination of these types of behaviors (Wang, Iannotti & Nansel, 2009).

In our previous review, we highlighted the lack of a “gold standard” definition for cyberbullying, and questioned whether traditional bullying criteria should be used for conceptualizing cyberbullying (Wingate, Minney & Guadagno, 2013). Recent research has addressed this question; however, there is a lack of consensus about how cyberbullying is related to traditional bullying (Olweus, 2012). A number of studies, mainly cross-sectional in design, have shown that traditional and cyberbullying behaviors, as well as victimization, sometimes co-occur (e.g., Beran & Li, 2007; Cross et al., 2009; Hinduja & Patchin, 2008; Kowalski, Morgan & Limber, 2012; Raskauskas & Stoltz, 2007; Smith et al., 2008; Vandebosch & Van Cleemput, 2009). A meta-analysis of empirical research on cyberbullying confirmed there is a consistent significant relationship between cyberbullying and traditional bullying; individuals who bully face-to-face tend to also engage in cyberbullying (Kowalski, Giumetti, Schroeder & Lattanner, 2014). Other research has found that cyberbullying seems to function in much the same way as traditional bullying, at least in regards to the deleterious effects it has on students’ self-esteem (Olweus, 2012). Because of the overlap in face-to-face and cyberbullying behaviors, programs aimed at reducing traditional bullying may also reduce cyberbullying (Salmivalli, Kärnä & Poskiparta, 2011).

The findings reviewed above are consistent with Olweus’s (2013) assertion that cyberbullying is just a new spin on an age-old behavior. One proposed model for understanding the relationship between cyberbullying and traditional bullying considers the medium (face-to-face or cyber) as a dimension of aggressive behavior (Mehari, Farrell & Le, 2014). In this model, there are two dimensions: (1) type: verbal, relationship and physical, and (2) medium: cyber or in-person. This proposed conceptualization acknowledges that there may be characteristics unique to cyberbullying, such as the potential anonymity of the perpetrator, but also recognizes that cyberbullying shares many behaviors and consequences with traditional forms of bullying (Mehari et al., 2014).

While there is undeniable overlap between cyberbullying and traditional bullying, there are features unique to cyberbullying that must be considered and addressed by any successful intervention or prevention program. A series of studies by Pieschl, Kuhlmann, and Porsch (2015) included the three traditional bullying criteria (intent, power differential, and repetition) as well as three features potentially specific for understanding cyberbullying: (1) media: whether the bullying was in written or pictorial form, (2) publicity: whether the incident was private (e.g., a private message on Facebook), semi-public (e.g., a post in a closed Facebook group), or public (e.g., a public post on Facebook), and (3) type: denigration (spreading rumors), exclusion (from online groups and activities), harassment (threats, insults, slurs, etc.), impersonation (bullies passing themselves off as someone else), or outing (revealing secrets to others). In these studies, students rated attributes for each of the six factors in terms of how much distress they imagine a victim of cyberbullying would feel. Results revealed that the type of bullying incident, how public the incident was, and the frequency of cyberbullying were the most important factors for distress (Pieschl et al., 2015). Increased frequency was associated with increased distress, as was increased publicity (the more public an incident, the more distressing it was perceived to be); outing of secrets to others was consistently rated as the most distressing type, but not all students considered outing to be cyberbullying (Pieschl et al., 2015). When asked about what they considered cyberbullying, up to 25% of students did not consider private communications to be cyberbullying. Additionally, in one study, students rated

incidents by anonymous perpetrators as more distressing than unpopular or popular perpetrators, but this pattern of results was not consistent across the three studies (Pieschl et al., 2015). It may be that the identity of the perpetrator interacts with another factor, such as type, or that these inconsistent results were the result of cohort effects (samples in studies 2 and 3 were older). Future research should address whether anonymity is more distressing for certain types of cyberbullying; for example, when secrets are being revealed, the victim may logically assume the perpetrator is a close friend, and the inability to identify an anonymous source could be immensely distressing.

Research continues to emerge that suggests a comprehensive understanding of cyberbullying needs to move beyond the three traditional criteria for bullying. While the status of the bully still remains a relevant criterion, an anonymous perpetrator could be as distressing to a victim as a high status one. Additionally, the degree of publicity involved is clearly important for understanding the magnitude of the distress caused by cyberbullying. Given that up to 25% of students in the Pieschl et al. (2015) studies did not consider private communications to be cyberbullying, future psychoeducational approaches should consider addressing this as part of the curriculum.

MOTIVATIONS FOR CYBERBULLYING AND VICTIM SELECTION

Peoples' normative beliefs and values are shaped by the influence of those in their social network (Farmer, Pearl & Acker, 1996). Students who engage in bullying behavior do so because people in their social network reinforce the behavior. Some have suggested that bullies target their victims because they are mimicking behaviors seen as part of a troubled home life, but recent research has shown that the primary motivation for bullying is to increase social status (Faris & Ennett, 2012; Sijtsema, Veenstra, Lindenberg & Salmivalli, 2009; Veenstra, Lindenberg, Munniksma & Dijkstra, 2010). Many bullies have well-developed social skills and can even be popular—the movie cliché of the “popular bully” reflects what research has shown (Sutton, Smith & Swettenham, 1999).

Aggression tends to increase as students climb the social ladder, and peaks just before the top of the social hierarchy (Faris & Felmlee, 2011). Popular students may use relationally and physically aggressive tactics, such as bullying a potential social rival, to maintain their social dominance (Cillessen & Mayeux, 2004; Garandeau, Ahn & Rodkin, 2011; Juvonen, Graham & Schuster, 2003; Luthar & McMahon, 1996). However, students at the very top of the social hierarchy have been found to be among the least aggressive students, perhaps because there is no further social status for them to gain (Faris & Felmlee, 2011). Research has also found that there is greater peer pressure for students near the top of the social hierarchy; students may feel pressured to use bullying and other aggressive strategies to maintain their social status (Cillessen & Schwartz, 2011; Faris & Felmlee, 2014; Haynie, 2001; Schwartz & Gorman, 2011).

There are two different strategies used by bullies to select victims: normative and instrumental targeting. Normative targeting occurs when bullies target peers based on characteristics of the victim; this has the additional effect of reinforcing social norms. Biff (from *Back to the Future*) engages primarily in normative targeting when he bullies the nerdy, scrawny George McFly. Research has shown that certain socially stigmatizing characteristics

increase the likelihood that students will be victims of bullying. Some common examples of socially stigmatizing characteristics are: acne (Sweeting & West, 2001), having a disability (Rose, Monda-Amaya & Espelage, 2011), being overweight or underweight (Wang, Iannotti & Luk, 2010), or being less developed physically (mainly males) (Batsche & Knoff, 1994; Olweus, 1993). Students who are lesbian, gay, bisexual, or transgendered (LGBT), or are perceived to be LGBT, are significantly more likely to be victims of bullying (Katz-Wise & Hyde, 2012). One study found that 38% of non-heterosexual female students and 30% of non-heterosexual male students were victims of cyberbullying at some point, while only 24% of heterosexual females and 15% of heterosexual males experienced cyberbullying (Hinduja & Patchin, 2011). While LGBT students may be victimized as a result of normative targeting, bullies may use cyberbullying of these students to gain or maintain social dominance, which is characteristic of instrumental targeting. In contrast to Biff, Regina (from *Mean Girls*) engages primarily in instrumental targeting; she bullies to maintain her social dominance, and her victims do not necessarily have targetable attributes (Brown & Hearnstein, 1975; Cairns, 1979; Faris & Ennett, 2012). Although this has not been studied empirically, anecdotal evidence suggests that victims of cyberbullying are chosen through a combination of normative and instrumental targeting.

Another process that contributes to victim selection is social contagion; victimization can spread through friend groups, so students who associate with victims can become victims themselves (Faris & Felmlee, 2014). Sometimes, to avoid being victimized themselves, students will cyberbully their friends. This seems to occur more frequently within female friend groups than in male friend groups, which is consistent with research showing that females use relationally aggressive tactics more often than physical ones (Cassidy, Brown & Jackson, 2011; Cassidy, Jackson & Brown, 2009; Cassidy, Faucher & Jackson, 2013; Patchin & Hinduja, 2012).

CHALLENGES TO PREVENTION AND INTERVENTION FOR CYBERBULLYING

Cyberbullying presents several unique challenges for researchers and others looking to develop effective programs to reduce and prevent it. First of all, cyberbullying can be covert; parents and teachers may not be aware that a student is being cyberbullied, or how severe it is. However, what is more problematic for the development and implementation of effective interventions is teachers' attitudes towards cyberbullying. A recent study of high school teachers at an urban high school in the United States found that nearly 25% of teachers were neutral or disagreed with the statement "Cyberbullying has long-lasting negative effects," and the same percentage were neutral or agreed with the statement "cyberbullying prepares students for life" (Stauffer, Heath, Coyne & Ferrin, 2012). More than half of the teachers were unsure or opposed to a formal cyberbullying prevention program being implemented at their school (Stauffer et al., 2012). This presents a significant barrier to implementation because teacher cooperation and participation is essential for program integrity and effectiveness.

In contrast, most students consider cyberbullying to be just as harmful as traditional bullying (Slonje & Smith, 2008; Smith et al., 2008). A recent study even found that students perceive cyberbullying as worse than traditional bullying, perhaps because of the potential for

a much larger audience (Sticca & Perren, 2013). Researchers manipulated features of bullying scenarios and asked students to rank the scenarios in order of severity; students reported perceiving public scenarios as worse than private ones, and anonymous scenarios as worse than ones that were not anonymous (Sticca & Perren, 2013). This research sheds crucial light on how the unique features of the cyber medium (potential anonymity and audience) contribute to students' perceptions of the severity of a bullying incident. Cyberbullying has consistently been associated with negative outcomes for both bullies and victims; it can result in anger and frustration (Hinduja & Patchin, 2007, 2010), depression and fear (Kowalski, Limber & Agatston, 2008; Raskauskas & Stoltz, 2007), and can unfortunately even serve as a catalyst for suicide (Hinduja & Patchin, 2010; Kowalski et al., 2008). Given that students perceive cyberbullying as a problem, and the growing body of research demonstrating it has long-lasting negative consequences for students, the development of effective programs to prevent and reduce cyberbullying is essential.

Another consideration for intervention and prevention is the age when cyberbullying behaviors first occur, and at what age these behaviors tend to peak, in order to determine when prevention and intervention programs will be the most effective (Kowalski et al., 2014). Research regarding when cyberbullying begins and escalates is mixed, but there is some consensus that it begins in earnest after elementary school. Some studies have found cyberbullying is highest among 15-17 year olds (Ybarra & Mitchell, 2004), while others suggest cyberbullying is highest among middle school students, relative to high school students (Slonje & Smith, 2008). Still others have found that cyberbullying behaviors increase in frequency with age, starting in middle school (Kowalski & Limber, 2007).

Although the consensus is that cyberbullying rates are highest in the adolescent and pre-adolescent years, some researchers have suggested that prevention programs be implemented earlier because cyberbullying has also been reported in elementary schools (Tangen & Campbell, 2010). Early intervention in elementary school could decrease the incidence of cyberbullying and reduce its impact in middle and high school. Results are conflicting as to the optimal age for anti-bullying interventions. Traditional anti-bullying interventions have been shown to be most effective with younger students (Rigby & Slee, 2008); however, a recent meta-analysis by Ttofi and Farrington (2011) revealed that anti-bullying interventions increase in effectiveness as students age. Unfortunately, regardless of initial results, changes to student behavior do not persist over time as a result of traditional anti-bullying programs (Ferguson, Miguel, Kilburn & Sanchez, 2007).

TRADITIONAL ANTI-BULLYING PROGRAMS

One approach to combatting cyberbullying is to use existing anti-bullying programs and include content specifically addressing cyberbullying; another approach is to use a program specifically designed to prevent and reduce the incidence of cyberbullying. We will briefly review and summarize the research on traditional anti-bullying programs, and discuss what can be learned from these programs about prevention and intervention for cyberbullying.

A whole-school approach to bullying prevention constitutes everyone in the school's ecology (e.g., students, parents, community, teachers, staff) working together to combat bullying. For traditional bullying, whole-school interventions *might* be the most effective way

to address existing bullying, and prevent further bullying, by utilizing a joint prevention and intervention approach that will not stigmatize students (Cross, Brown, Epstein & Shaw, 2010; Rigby & Slee, 2008; Smith, Ananiadou & Cowie, 2003; Stevens, Bourdeaudhuij & Van Oost, 2001; Vreeman & Carroll, 2007). However, the effectiveness of such programs can vary widely depending on implementation fidelity (Farrington & Ttofi, 2009b; Urbis Proprietary Limited, 2011). A meta-analysis of 44 school-based anti-bullying programs from 1983 to 2009 found, on average, such programs reduced traditional bullying by 20-23%, and reduced victimization by 17-20% (Ttofi & Farrington, 2011). The most important elements for reducing victimization were collaborative group and peer work, parent training, disciplinary measures and educational videos (Ttofi & Farrington, 2011). Program elements that were identified as crucial to reducing bullying were classroom rules and management, parent training and information, videos, school assemblies, disciplinary measures and heightened playground supervision (Farrington & Ttofi, 2009a, 2009b).

SCHOOL-BASED ANTI-CYBERBULLYING CURRICULUMS

A significant body of research has suggested that effective programs to reduce and prevent cyberbullying need to be school-based and include education for school employees, as well as students (Agatston, Kowalski & Limber, 2012; Cassidy et al., 2011, 2012, 2012b; Collier, 2012; de Santo & Costabile, 2012; Donlin, 2012; Grigg, 2010; Jackson, Cassidy & Brown, 2009; Jäger, Amado, Matos & Pessoa, 2010; Marczak & Coyne, 2010; Patchin & Hinduja, 2011; Perren et al., 2012; Sakellariou, Carroll & Houghton, 2012; Tangen & Campbell, 2010; Topçu & Erdur-Baker, 2012). Two surveys of middle and high school students asked what they thought would be the best way to reduce cyberbullying; in both surveys, students ranked education on what cyberbullying is and what its effects are among their top suggestions (Cassidy et al., 2011). Their parents agreed; the parent survey revealed they want schools to implement a cyberbullying education program and facilitate a dialog with their children about cyberbullying and its effects (Cassidy, Brown & Jackson, 2012a). Other researchers have suggested that cyberbullying curriculum should include information about how students should conduct themselves online to protect their privacy and reputations (Agatston et al., 2012; Collier, 2012; Grigg, 2010; Marczak & Coyne, 2010; Perren et al., 2012). This seems beneficial considering one study found that only 15.4% of students who were considered digitally literate and had knowledge about e-safety learned it at school (Yilmaz, 2011).

In this section, we will review the research on some of the available curriculum-based school programs specifically designed to address cyberbullying: i-SAFE Internet Safety Program (i-SAFE Inc., 1998), “Let’s Fight It Together: What We All Can Do to Prevent Cyberbullying” (Childnet International, 2007), Cyberbullying: A Prevention Curriculum (Kowalski & Agatston, 2008, 2009), and Sticks and Stones: Cyberbullying (Wilson, 2009). Unfortunately, our literature review yielded limited research supporting any of these interventions as being effective methods of reducing or preventing cyberbullying.

i-SAFE Internet Safety Program

The i-SAFE Internet Safety Program is a cyberbullying prevention curriculum for students in kindergarten through 12th grade. It is primarily professional development training, available via a subscription service, which teaches authorities (e.g., school personnel, community leaders, parents) how to teach the curriculum (i-SAFE Inc., 1998, 2009). The i-SAFE curriculum varies based on developmental cohort. The youngest cohort (grades K-4) learns vocabulary about the Internet and participates in hands-on safe Internet use. The middle cohort (grades 5-8) is exposed to preventive and intervention methods of cyberbullying by engaging in discussions and applicable activities. Finally, the oldest cohort (grades 9-12) includes the same concepts as the younger cohorts, but the discussions and activities about safety and intervention and prevention are built around videos (Webcast) (i-SAFE Inc., 1998, 2009). i-Safe was one of three short-term cyberbullying intervention programs included in a review of classroom-based anti-cyberbullying programs. Although it did not result in a change of attitudes or behaviors related to cyberbullying, it did result in increased student knowledge about online safety (Mishna, Cook, Saini, Wu & MacFadden, 2009). Our literature search found no other empirical studies on the efficacy or effectiveness of i-SAFE in reducing or preventing cyberbullying; however, it is a comprehensive education program about Internet safety and cyberbullying, and future research may support its use.

Cyberbullying: A Prevention Curriculum

Cyberbullying: A Prevention Curriculum is an eight-session program for students in grades 6 through 12 on cyberbullying (Kowalski & Agatston, 2008, 2009). Sessions include the ramifications of being a cyberbully, and how students can provide help to victims if they see cyberbullying happen. It includes support materials such as posters, a CD-ROM, handouts, and video vignettes that are given to parents to elicit discussion. There is also a version for lower grades that was created a year after the initial launch of the prevention curriculum (Kowalski & Agatston, 2008, 2009). This program is based on the Olweus Bullying Prevention Program, and can be included as part of a broader effort to reduce all types of bullying (Limber, Kowalski & Agatston, 2009). Although we did not find any empirical data supporting this program's effectiveness in reducing or preventing cyberbullying, a meta-analysis of traditional anti-bullying programs found that the most effective programs were the ones based on the Olweus curriculum (Ttofi & Farrington, 2011).

Other Cyberbullying Programs

With the broad media attention paid to cyberbullying, a number of less widely known programs have cropped up, seemingly overnight. Unfortunately, as with the programs reviewed above, no data was available to support the effectiveness of these programs in reducing or preventing cyberbullying. These programs are briefly described below.

Sticks and Stones: Cyberbullying is for grades 9-12 which consists of a film that shows a student being cyber victimized. It comes with a discussion guide for teachers to help facilitate a dialog with students about the film (Wilson, 2009).

“Let’s Fight It Together: What We All Can Do to Prevent Cyberbullying” is a cyberbullying curriculum developed for students aged 11-14 years old, but can be used for ages 10-18 years old. It is a curriculum comprised of video segments to be viewed with peers in a classroom, or larger school setting, and is accompanied by discussion guides and lesson plans for teacher to guide follow-up (Childnet International, 2007).

The Anti-Defamation League has created lesson plans online for high school students (Cyberbullying and Online Cruelty: Challenging Social Normals; Anti-Defamation League, 2008a, 2008b), for middle school students (Dealing with the Social Pressures that Promote Online Cruelty; Anti-Defamation League, 2008b), and even elementary school students (“Building a Foundation for Safe and Kind Online Communication”; Anti-Defamation League, 2008a). There were also workshops created for parents, school administrators, and teachers: “Youth and Cyberbullying: What Families Don’t Know Will Hurt Them” (Anti-Defamation League, 2008b) and “Trickery, Trolling, and Threats: Understanding and Addressing Cyberbullying (Anti-Defamation League, 2008c).

Strategies for Improving School-Based Education about Cyberbullying

Some school administrators and teachers may know less than their students about technology and social networking (Cassidy et al., 2012b), so it may be helpful for school systems to incorporate media education into the curriculum (Cassidy, et al., 2013). As media and technology continue to develop, this curriculum would need to develop with it to address media’s new characteristics, such as personalization, the portability of devices, and increased social media access (de Santo & Costabile, 2012). One way to ensure a flexible curriculum that meets students’ current needs is to actively include students in creating the media education curriculum; this could improve students’ buy-in and their perception of the curriculum’s relevancy (Cassidy & Bates, 2005).

Another strategy for combatting cyberbullying is to address the unique features of cyberbullying indirectly. This could include better psychoeducation for students on how to protect themselves in a digital world (Collier, 2012). One unique characteristic of cyberbullying is the distance between the bully and victim, which prevents the bully from seeing the consequences of the bullying behavior. In traditional bullying, the victim’s reaction can evoke empathy in the bully, which can mitigate the severity of the bullying—this does not occur in cyberbullying (Topçu & Erdur-Baker, 2012). Some research has suggested that if students are made aware of how victims of cyberbullying suffer, they are less likely to engage in cyberbullying (Davis & Nixon, 2012). Interventions that include specific empathy education as a component may be more effective than psychoeducational approaches alone (Topçu & Erdur-Baker, 2012); however, for empathy education to be successful it is crucial that students see empathy modeled for them by teachers and school administrators (Cassidy & Bates, 2005; Noddings, 2002, 2005).

ALTERNATIVES TO CURRICULUM-BASED CYBERBULLYING PREVENTION

Although curriculum-based programs seem to be the most common approach to combatting cyberbullying, there are several alternatives worth mentioning. Relative to traditional bullying, there are likely to be far more bystanders witnessing cyberbullying, and some researchers have focused their efforts on these bystanders, rather than the bullies or victims. Other programs are peer-led, and emphasize student participation instead of teacher-delivered content. A final approach is legislative, and focuses on advocating for legal protection against cyberbullying, and avenues to prosecute perpetrators.

Bystander Interventions to Reduce Cyberbullying

There are several ways students can be bystanders of cyberbullying behavior—they can see the hurtful messages on a website, a hurtful message could be forwarded to them, or they could be physically present when the message is sent by the bully or received by the victim (Li, Smith & Cross, 2012). Several empirical studies have been conducted to assess when and how bystanders intervene in cyberbullying (i.e., Bastiaensens et al., 2014; Desmet et al., 2012; Dillon & Bushman, 2015). From these studies, it appears that students are more likely to directly intervene with the victim by giving advice or offering comfort, rather than intervening directly with the bully. This type of social support may be comforting to the victim, but does not decrease the likelihood of future victimization. Rates of bystander intervention were higher when the cyberbullying incident was perceived to be more severe, especially if the bystander's close friends also witnessed the incident (Bastiaensens et al., 2014). In one study, participants engaged in an online chat with several confederates, one who was purportedly the chat monitor, and one who was the victim. The chat monitor bullied the victim-confederate during the chat. At the end, participants were given the opportunity to evaluate the chat, and the chat monitor (bully); poor ratings of the monitor and/or chat was considered indirectly intervening with the bully (Dillon & Bushman, 2015). This is analogous to reporting an offensive or harassing post on Facebook because the bully remains unaware of who reported the incident, but the offensive post is likely to be removed by Facebook administrators. This sort of indirect intervention is low-risk to the bystander, but offers no direct support to the victim.

Victims of cyberbullying often disclose the bullying to their friends, so if students are given adequate education about how to intervene in cyberbullying they could provide valuable social support to victims (Cassidy et al., 2009, 2011; Smith, 2012). Bystander education should include both direct and indirect methods of intervention, as well as strategies to protect themselves from retaliation (Perren et al., 2012). By offering social support to victims, and reporting bullying behavior to appropriate authorities, bystanders can mitigate the effects of bullying and potentially prevent future incidents (Cassidy, et al., 2013; Salmivalli, 2010).

Peer-Led Programs to Reduce and Prevent Cyberbullying

Change in social norms and behavior are most likely to be achieved when the perceived leaders of the target group are directing the change (Maticka-Tyndale & Barnett, 2010; Naylor

& Cowie, 1999; Turner & Shepherd, 1999). Student involvement in program development could prove invaluable in creating effective programs to combat cyberbullying with high student buy-in (Wong, Zimmerman & Parker, 2010).

Empirical studies of an Italian intervention program to reduce and prevent cyberbullying (*Noncadiamointrappola*; Menesini & Nocentini, 2012) have found promising effects for peer-led intervention, including significantly decreased traditional victimization, cyber victimization, and bullying. In this program, some students were designated as peer educators, and attended training as interventionists. These student leaders actively facilitated change in their classrooms through leading discussions and activities, and creating a supportive Facebook group (Menesini & Nicentini, 2012; Palladino, Nocentini & Menesini, 2012). The program also resulted in changes in the coping strategies employed by students, specifically higher rates of problem-solving and less avoidance (Palladino, et al., 2012). The intervention did not result in significantly increased social support for victims, but cyber victimization did decrease (Palladino, et al., 2012).

Anti-Cyberbullying Legislation

Legislation addressing cyberbullying should not be considered a substitute for prevention and intervention; however, if intervention and prevention efforts have failed, it offers a legal mechanism for prosecuting perpetrators.

Snakenborg, Acker and Gable (2011) summarized the state of the legislation that has passed in the United States regarding cyberbullying. Congress passed legislation called “Protecting Children in the 21st Century” in 2008, and it includes provisions about cyberbullying. According to the Anti-Defamation League (2009) and National Conference of State Legislatures, 44 states have passed varying legislation on intimidation, harassment, and bullying in schools. Because of the definitional problem for cyberbullying and what constitutes cyberbullying behaviors, some states have implemented broad legislation to address any behaviors that could potentially be considered cyberbullying. In 2009, North Carolina made cyberbullying a misdemeanor with the “Protect Our Kids” bill. In Missouri, engaging in cyberbullying can result in penalties ranging from being fired from a job, to jail time (Stroud, 2009). Ohio, Virginia, and other states have addressed cyberbullying by manipulating already existing legislation on bullying to account for cyber forms of bullying (Snakenborg, et al., 2011).

To assist the states in creating their own cyberbullying policies, The Anti-Defamation League created a model the states can use. This model includes the following infractions: privacy breach (disclosure of a private piece of information to the public), defamation, lying about an individual to make him/her look bad publicly, and purposefully causing emotional strain (see Snakenborg, et al., 2011). Although legislation addressing cyberbullying is a positive development, the lack of consistency across states in terms of what constitutes cyberbullying and punishments for the behavior can evoke confusion in victims. Cyberbullying victims understand that their abuse was hurtful, but they would also have to evaluate the cyberbullying to infer whether it constitutes legal action.

STRATEGIES FOR VICTIMS TO COPE WITH CYBERBULLYING

There seems to be a lot of *unhelpful* advice out there for students on how to cope with cyberbullying. The following is a list of strategies that are *not* recommended:

1. Telling cyber victims to not worry about it, and to avoid the website where the cyberbullying is happening, or suggesting the victim change their username/email address (Tokunaga, 2010). These kinds of avoidance strategies do nothing to prevent future victimization and do not teach students appropriate coping skills.
2. Suggesting the victim directly confront the bully, either by telling the bully to stop, or suggesting the victim intends to report the bully (Tokunaga, 2010). This strategy has been shown to exacerbate the problem, rather than solve it (Perren et al., 2012).
3. Encouraging the victim to talk about cyberbullying and the cyberbully on message boards or anonymous websites, or even to cyberbully the perpetrator (Monks, Robinson & Worlidge, 2012; Smith & Slonje, 2010). There is a lack of clear empirical evidence that any of these options actually work, and encouraging retaliatory aggressive behavior is likely to *increase* future victimization, rather than decrease it (Perren et al., 2012).

Coping strategies that increase the victims' feelings of control in cyberbullying situations are more likely to be successful, and facilitate the development of appropriate social skills (König, Gollwitzer & Steffgen, 2010). Healthy strategies for coping with cyber victimization should focus on increasing the victim's competencies and resiliency, rather than avoidance of the situation or retaliation against the perpetrator.

Resilience is the ability to function through life's trials in an adaptive way, which can thereby become a pattern (Masten, Best & Garmezy, 1990; Wright & Masten, 2005). *Online resilience* refers to being equipped to handle negative online experiences through active problem solving rather than passivity, avoidance, or retaliation (Vandoninck, d'Haeneas & Roe, 2013). Research has shown youths cope adaptively with negative experiences online by seeking out friends' support (Nycyk, 2011), being digitally literate about protecting themselves (Vandoninck, d'Haemeas & Segers, 2012), sharing information about the harmful communication (Kochenderfer-Ladd & Skinner, 2002), and talking to an adult about cyberbullying incidents (Livingstone, Hadden, Görzig & Ólafsson, 2011).

A SOCIAL-ECOLOGICAL APPROACH TO CYBERBULLYING PREVENTION AND INTERVENTION

The Social Ecological Framework (Bronfenbrenner, 1977) conceptualizes bullying as a group phenomenon that occurs when several factors interact with each other across time. In this nested model of factors, the individual is the innermost system, followed by the microsystem, which consists of family, peers and the school. The third level is the macrosystem, which includes the student's larger community; the outermost level, the exosystem, includes socio-cultural influences (Bronfenbrenner, 1977). A key assumption of the Social Ecological Framework is that systems have reciprocal effects on each other. Students both influence their

environment through their interactions with peers, school staff, and family, and also are influenced by these interactions.

Swearer et al. (2006) conducted tests of a social-ecological model of bullying; in their model, bullying is the result of the combined influence of individual, peer, family, school, and community factors. Individual factors (i.e., negative affect, depression, and aggression) have reciprocal effects on others in the students' social networks, while peer factors (i.e., prior victimization, and peers rewarding bullying with status) and family factors (i.e., bullying at home and socioeconomic disadvantage) may act to reinforce bullying behaviors (Swearer et al., 2006). School factors (i.e., perceiving a negative school climate), and community factors (i.e., crime statistics, and being bullied en-route to and from school) may create a culture where students do not feel safe and aggressive behaviors are actually adaptive for survival (Embry, 2004). In an initial test of this model, researchers found that students who engage in bullying and/or are victimized reported more positive attitudes about bullying, and perceived their school climate as being more negative (Swearer et al., 2006). Subsequent research has provided further support for a social-ecological model for understanding bullying.

In a large study of 27 schools, bullying perpetration and victimization was moderated by a positive school climate, and predicted by substance use and depression (Espelage & Swearer, 2009). Less bullying perpetration was associated with having a positive peer group and caring parents; however, for students who reported low parental caring and low positive peer support, a positive school climate served as a buffer against the negative effects of these influences (Espelage & Swearer, 2009). For students who do not have positive peer or parent models, having positive relationships with teachers and a sense of academic efficacy may lower their likelihood of perpetrating bullying. To reduce the levels of bullying perpetration and victimization, Espelage and Swearer (2009) recommend the implementation of school-based interventions that specifically focus on creating a positive school climate, improving students' sense of closeness with teachers, and nurturing academic competencies.

The prevailing logic of current bullying prevention programs, both curriculum-based and peer-led, is that educating students about bullying and cyberbullying will result in changes in students' knowledge and behavior. However, these programs do nothing to modify the environmental variables that contribute to bullying. Such psychoeducational approaches are inconsistent with the recommendations cited above by Espelage and Swearer (2009), and these approaches treat bullying as the problem itself, rather than the result of multiple influences in students' environments. An ecological approach to bullying prevention would necessarily be long-term, and involve parents, students, teachers, and the community at large. The goal would be to create a school culture that promotes pro-social behaviors, and discourages bullying by not rewarding it with increased social status and peer approval.

One example of a social-ecological approach that has been shown to reduce bullying is the PAX program. PAX is a school-based program that has been recognized for its cost-effectiveness, as well as for the broad, long-lasting impact it has on students (Embry & Richardson, 2012). The PAX program uses evidence-based kernels (individual units of behavioral change) to modify the school environment of children from kindergarten through sixth grade, with effects lasting through adolescence, and creates a school culture that facilitates pro-social behavior and improves student outcomes. Data on the effects of the PAX program from studies conducted at Johns Hopkins has revealed that it resulted in decreased aggression and antisocial behavior, including bullying, reduced rates of substance abuse, and reduced symptomology of Attention Deficit/Hyperactivity Disorder and Oppositional Defiant Disorder

(Embry, 2009). Positive outcomes of the PAX program included improved reading skills, and lifetime academic achievement, including higher rates of high school graduation and college entry (Embry, 2009). Some of the active program elements that may specifically act to reduce bullying include “Tootles” or “PAX-it Notes,” (similar to a Post-It note) which are written peer-to-peer praises for pro-social and on-task behavior that are posted in a public area at school. There are other opportunities for public social recognition; for example, students can be named as PAX Leaders and help coach their peers toward appropriate behavior (Embry & Richardson, 2012).

A core element of the program is the PAX game, formerly known as the Good Behavior Game, which utilizes group-based contingencies to improve classroom behavior. In this way, peer pressure becomes a force for positive change; students want to win the game, so they encourage appropriate behavior, and refrain from encouraging negative behavior (Embry, 2009). So, for example, if a student was to engage in bullying, bystanders would be less likely to participate or “egg on” the bully, because that would result in additional marks against their team, and they would lose the game. When peers ignore negative behavior and fail to reinforce it, the motivation to engage in such behavior again is greatly reduced (Embry, 2004; Embry & Richardson, 2012).

The evidence-based kernels employed in the PAX program could be widely implemented by parents, and in the community at large to result in broad changes to students’ social ecology, and increase the effectiveness of the program (Embry, 2004). For example, parents could employ “Tootles” (written praises for specific behaviors) at home, and the “Tootles” could be posted on the refrigerator as public reinforcement. An example of a community-based behavioral kernel is replacing traditional placemats in family-oriented restaurants with “table-talk” placemats that have topics for conversation and games for the whole family (Embry, 2004). In one study, table-talk placemats increased rates of social and educational conversations, reduced coercive comments from parents, and child distraction (Green, Hardison & Greene, 1984). These types of low-intensity interventions are also low-cost, but have the potential to considerably impact children if instituted in every facet of their environment. See Embry (2004) for a complete list of suggestions on how parents and communities can easily implement behavioral kernels to produce lasting change.

It is noteworthy that the PAX program never directly addresses bullying behavior, but remains a highly effective prevention program. To successfully prevent all forms of bullying and improve outcomes for all students, programs must move beyond psychoeducational models to ecological ones that modify the environment.

CONCLUSION

It is not our intent to discount the value of psychoeducational approaches to combat cyberbullying. Interventions that focus on improving students’ digital literacy, and teaching them how to protect themselves in an increasingly digital world, may impart important life skills to students. However, by itself, psychoeducation about cyberbullying is akin to treating strep throat with a cough drop—it treats the symptom, rather than the core problem. Cyberbullying and bullying are just some of the negative consequences resulting from the interaction of negative school climate, low parental caring, and the lack of positive peer support.

It is our assertion that interventions which *solely* target cyberbullying and/or bullying are not ambitious enough. If we focus our attention on bullying, and ignore the environmental and cultural factors that reinforce and maintain it, we are short-changing our children. Social-ecological programs, such as the PAX program, reduce bullying by targeting the underlying environmental factors (Embry, 2004). Because these underlying environmental factors are common to a multitude of poor outcomes (i.e., depression, substance abuse, low education achievement, violent crime and incarceration), one social-ecological program can affect change in multiple domains (Espelage & Swearer, 2003, 2009). Instead of schools having a program to prevent substance abuse, a program to prevent bullying, and a program to prevent depression, they can implement a single program.

Future research should evaluate the effectiveness of programs grounded in a social-ecological framework by specifically addressing cyberbullying perpetration and victimization. An additional consideration for research is to examine if the addition of psychoeducational components focused on bullying and cyberbullying increases the effectiveness of social-ecological programs. The development of several cyberbullying prevention and intervention strategies reflects the importance of reducing this harmful form of communication, and accumulating literature evaluating these strategies is pointing us in the direction of effectively addressing cyberbullying.

Chapter 21

IN SEARCH OF A SIMPLE METHOD: IS A HUMAN FACE AN EFFECTIVE, AUTOMATIC FILTER INHIBITING CYBERBULLYING?

Anna Szuster*, Julia Barlińska and Magdalena Kozubal

The Faculty of Psychology, University of Warsaw

INTRODUCTION

The Internet has become an indispensable part of everyday life, especially among adolescents, with 78% having a cell phone, 95% using the internet, and 37% having a smartphone (Lenhart, Purcell, Smith, Zickuhr, 2010; Madden et al., 2013). The almost inevitable consequence of young peoples' social functioning in cyberspace is the occurrence of both positive and negative experiences, including cyberbullying. Cyberbullying has been identified as a growing problem among adolescent internet users throughout the world (Smith, 2007; Smith, 2011; Dehue, 2013). The developmental tasks associated with adolescence make teenagers particularly susceptible to antisocial behavior on the Internet, including high egocentrism (Piaget & Inhelder, 1962), weak motivation for decentration (Piaget & Inhelder, 1962), reflection about oneself and one's behavior (Hoffman, 2000), moral relativism and the testing of moral principles (Kohlberg, 1976), unformed personal identity (Erikson, 1968), and the strong influence of peers (Hurrelmann, 1994).

This phenomenon has also proved difficult to define (Langos, 2012). Due to the ever-changing characteristics of new technologies, the classical criteria of bullying as including repetition and power imbalance become ambiguous in cyberspace (Dooley, Pyżalski, Cross, 2009). This makes the task of providing the precise definition even harder. One of the most commonly cited definitions of cyberbullying is "an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself" (Smith, 2007 p. 376).

* Corresponding Author's Email: hanka@psych.uw.edu.pl.

Recently, increasingly emphasis has been given to the importance of bystanders as powerful moderators in the process of both online and offline peer aggression (Ball, 2007; Barlińska, Szuster & Winiewski, 2013; Barlińska, Szuster & Winiewski, 2015; Kraft, 2011; Macháčková, Dedkov, Sevcikova & Cerna, 2013; Slonje et al., 2012; Salmivalli, 1999). Peers play a dominant role in the socialization of youth in both the offline and online environments (Hinduja & Patchin, 2013; Steinberg & Monahan 2007). Several authors have also stressed the need for considering bullying in terms of a group process (Gini et al., 2008; Caravita, Di Blasio & Salmivalli, 2009; Sutton & Smith, 1999; Salmivalli et al., 1996; Salmivalli, 2010). The focus on group processes further highlights the importance of bystanders as a powerful social influence when creating positive anti-bullying behavioral models and promoting positive choices in cyberbullying incidents. A program actively focused on bystanders, with an emphasis on their role and ways they react toward bullying seems to be an important element in preventing and reducing cyberbullying.

CYBERBYSTANDER TYPOLOGY

The behaviors of witnesses of bullying are never completely neutral (Garandeau & Cillessen, 2006). In a number of studies, bystanders have contributed to violence in various pro-bullying ways, such as acting as outsiders not helping the victim, and assistants or reinforcers that encourage the bully (Salmivalli et al., 1996; Andreou & Metallidou, 2004; Menesini, Codecasa & Benelli, 2003; Sutton & Smith, 1999). Such bystander actions further contributing to victims' harm aren't odd. Gini (2008) found that around 20-30% bystanders silently witness bullying episodes and do nothing. In another study, Sallmivalli and colleagues (1996) found that 20–30% of students in their study encouraged the bully, acting as assistants or reinforcers.

Bystanders to cyberbullying can also take an active role by participating in the victimization, especially by forwarding hurtful and denigrating content. Although data shows that the material is further distributed only by a minority of bystanders, technological advances allow for a single act of cyberbullying to be repeated many times by others, and to be experienced many times by the victim (Barlińska, Szuster & Winiewski, 2013; Barlińska, Szuster, Winiewski, 2015; Slonje et al., 2012). Bystanders' contribution to the repetition of cyberbullying acts creates the need to emphasize the indirect nature of these behaviors. In cases of indirect cyberbullying, the sender has no control over to who is forwarded the original communication (Langos, 2012). This makes it difficult to clearly differentiate between perpetrators' and negative bystanders' behavior (Boyd, 2007; Hinduja & Patchin, 2008).

In addition, the unique contribution of bystanders' ability to share a single incident of cyberbullying multiple times makes it different to understand the bystanders' role (assistant or reinforcer) in the incident. The role of the bystander is also complicated because some bystanders might choose to be inactive by deleting denigrating content and not reporting it. However, this action further contributes to victims' harm.

BYSTANDER REACTIONS IN COMPUTER MEDIATED COMMUNICATION

A consequence of computer-mediated communication is online anonymity of both the actor and the potential partner of the interaction (McKenna & Bargh, 2000; Christopherson, 2007). Anonymity on the Web facilitates deindividuation and reinforces self-presentation, while diminishing the sense of responsibility (McKenna, 2008). This leads to internet disinhibition (Joinson, 1998), which consists of the loss of self-control and the absence of restraints in socially unaccepted behavior typical of direct interactions (Suler, 2004). Consequently, people tend to act on the Internet in ways they would not in the face-to-face context. For instance, they might respond to aggressive messages by becoming offensive themselves, which fuels further aggression on the Internet.

Certain features of computer software induce impulsivity, which combined with the experience of computer games, forums, chat rooms, and social networking websites, causes adolescents to expect interactivity and being noticed, even at the cost of transgressing moral standards (Willard, 2006). This is only a small step from objectifying and exploiting others.

Behavior toward the “invisible” other lacks visual cues, which could modify the interaction (Suler, 2004). A lack of access to a whole host of information available in the face-to-face environment, such as facial expression, gesticulation, vocalization, eye contact, and physical distance, impairs automatic activation of empathy as an inhibitor of aggressive behaviour in cyberspace (Hoffman, 2000; Leather, 1997; Steffgen & König, 2009; Steffgen et al., 2012; Smith et al., 2008). Aggression is further escalated by limited feedback regarding the impact of online activity on other users, which produces the so-called “cockpit effect” (Heirman & Walrave, 2008). Online communication proceeds in distinctive conditions, which encourage incognizant aggression, often with the cyberbystander reinforcing cyberbullying by being unaware of the actual harm caused to the victim.

The Role of Cyberbullying Perpetration

Violence in cyberspace, just like in the real world, has an impact on the behavior of others. Many studies emphasize the links between offline and online bullying (Ybarra, Diener-West & Leaf, 2007; Erdur-Baker, 2010; Twyman, Saylor, Taylor & Comeaux, 2010). The perpetrators of cyberbullying were more likely to engage in offline violence and also participate in traditional bullying (Raskauskas, Stoltz, 2007; Slonje, Smith, 2007; Juvonen, Gross, 2008; Dehue, Bolman, Völlink, Pouwels, 2012; Sticca, Ruggieri, Alsaker, Perren, 2013; Ybarra & Mitchell, 2007). Furthermore, the various cyberbullying roles are related to bullying roles offline as well (Dehue, Bolman, Völlink, Pouwels, 2012, Smith et al., 2012, Smith, Slonje, 2010; Law, Shapka, Hymel, Olson, Waterhouse, 2012.). Sometimes the roles versus such that cyberbullies are often victims of online violence, while victims might also become online perpetrators (Ybarra & Mitchell, 2004; Walrave & Heirman, 2011).

As research on cyberbullying is fairly new, more information is known about violence and aggression in non-virtual environments. Past involvement in the perpetration of violence reinforces aggressive behavior through operant conditioning and modeling (Bandura, 1973). Additionally, if the violent behavior leads to any reward e (e.g., reduction of unpleasant mental states), it generally tends to become intensified. Exposure to online content might be a potential

new form of aggression, increasing the probability of enacting forms of violent behavior different from those presented by the model and raising the overall tolerance of violence (Parke, Slaby, 1983). The results of one of the few longitudinal studies on cyberbullying showed that engaging in behaviors that violate social norms predicted engagement in cyberbullying (Ybarra, Mitchell, 2004; Sticca, Ruggieri, Alsaker, Perren, 2013). In addition, cyberperpetrator has a profound impact on predicting cyberbystander behavior reinforcing cyberbullying (Barlińska, Szuster, Winiewski, 2013).

Bystander Behavior and Gender

The empirical findings of the relationship between gender and bystander behavior is mixed. Some research has revealed that girls tend to act more supportively and are more often nominated as defenders of face-to-face bullying than boys (e.g., Goossens et al., 2006; Menesini et al., 1997; Menesini et al., 2003; Oh & Hazler, 2009; Rigby & Slee, 1992; Salmivalli, Lagerspetz, Bjorkqvist, Osterman & Kaukiainen, 1996; Trach, Hymel, Waterhouse & Neale, 2010). Other research suggested that there are no gender differences in peer interventions in traditional bullying (e.g., Ball, 2007) or in cyberbullying (Li, 2006; Machácková, Dedkova, Sevcikova & Cerna, 2013; Barlińska, Szuster & Winiewski, 2013; Barlińska, Szuster & Winiewski, 2015).

Empathy and the Internet

Patricia Agatson (2014) claims that the key to solving the problem of cyberbullying is to establish digital citizenship in which a basic task would be to teach how to be good to one another. The interest in empathy fits in with the implementation of this idea.

Over one hundred years of philosophical reflection and psychological research on empathy has established empathy as a unique mechanism regulating social relations (e.g., Hume, 1739/1968; Smith, 1759/1976; Katz, 1963; Davis, 1996; Eisenberg & Steyer, 1987; Hoffman, 2000; Singer, de Vignemont, 2006). In addition, the eminent primatologist, Francis de Wall (2006), argues that chimpanzees demonstrate a nascent form of empathy as well. The foundation of empathy is intended communication the aim of which is to transmit, receive, and understand information about affective states of others. Most recent empirical findings have shown that as many as ten neural circuits in the brain are involved in processing empathy (Baron-Cohen, 2011). Research on empathy disorders has revealed the complexity of its underlying neural mechanisms. The symptoms of empathy deficiencies are different in borderline personality disorders, autism, Asperger's syndrome, and psychopathy, since it depends not only on individual circuits, but also on interconnections between them.

Empathy (both affective and cognitive) occurs “when we suspend our single-minded focus of attention, and instead adopt a double-minded focus of attention” (Baron-Cohen, 2011, p. 31). The majority of approaches today insist on the distinction between the person perceiving and receiving emotions and the person actually experiencing it, as well as the active quality of the process of empathy. This is what makes empathy different from the basic phenomenon of “emotional contagion,” although the latter is an important component of the former. There is, however, more to empathy: it introduces certain “filters” between one’s own and somebody else’s emotional state (Eisenberg & Strayer, 1987; de Waal, 2006).

The innate, automatic capacity to respond with empathic arousal to the discomfort of others is a basic, species-wide human trait. We do not learn to perceive another person's sadness or joy. Direct contact ensures access to species-universal information: stimuli that activate the mechanisms of affective empathy. In terms of development, the earliest mechanisms of empathic arousal are the circular reaction and motor imitation. Later, responses to another person's circumstances become increasingly governed by cognitive factors – and cognitive empathy develops. Defined as the ability to understand the beliefs, feelings, and intentions of others (Decety & Jackson, 2004), cognitive empathy involves more complex cognitive processes (Hoffman, 2000), and, consequently, mechanisms of triggering empathy. Through classic conditioning and association, other people's perceived emotions can be related to our own past experiences by virtue of similarity. With language-mediated association, empathic arousal becomes independent from present or past contact with another person. The most advanced mechanisms are role-taking and cognitive sense of others. The former requires the observer to make conscious effort to imagine how they would feel in a similar situation. The latter enables cognitive representations of others to be formed in the mind. These representations are the prerequisite for responding with empathy to others, recognizing them as sovereign individuals equipped with unique traits, beliefs, experiences, and internal states. These attributes of others are independent of a particular set of circumstances. They enable us to generalize from specific situations and to make predictions about other people's experiences in life. We are able to anticipate the consequences our actions have for other people. Cognitive empathy is a source of affect, but of a different, post-cognitive nature, due to the differences in information processing on the neural level between affective and cognitive empathy. Affective empathy triggers bottom-up processing, while cognitive empathy activates top-down processing.

Affective empathy is to a large extent genetically determined (Matthews, Batson, Horn & Rosenman, 1981; Rushton, Fulker, Neale, Nias & Eysenck, 1986; Zahn-Waxler, Robinson & Emde, 1992). By contrast, the development of cognitive empathy is driven primarily by environmental factors (Baron-Cohen, 2011). It is likely that cognitive empathy responses, especially role-taking, are shaped by environmental factors, e.g., parental influence. Modeling, the use of induction and perspective-taking are often mentioned as parenting techniques that facilitate the development of cognitive empathy (Hoffman, 2000). And while affective empathy is part of our human "standard equipment," cognitive empathy is an ability that may but does not have to be developed.

Perhaps the most frequently mentioned aspect of empathy is its social significance. A large body of empirical data confirm the benefits of dispositional and situation-dependent empathy. It has been associated with morality, altruism, fairness, prosocial behavior, and cooperativeness (Batson & Shaw, 1991; Eisenberg & Morris, 2001; Hoffman, 2000). Empathy has been shown to promote positive attitudes towards members of stigmatized groups, such as AIDS sufferers, homeless people, criminals, and minorities (Batson, 1997; Clore & Jeffrey, 1972; Vescio, Sechrist & Paolucci, 2003). Empathy makes us more aware of the needs of others, while prompting us to consider long-term consequences of offering help. As a result, the support of individuals with higher dispositional empathy is less dependent on immediate situational factors, such as the ease of reinterpreting the circumstances of others and mood (Batson, Dyck, Brandt, Batson & Powell, 1988; Batson et al., 1989). Situational arousal of cognitive empathy (with the "imagine...." cue) reduced negative stereotyping based on age (Galinsky & Moskowitz, 2000).

Empathy is positively correlated with the regulation of emotions and emotional behavior (Eisenberg, 2000), and negatively with the severity and frequency of negative emotions (Davis, Conklin, Smith & Luce, 1996). It provokes the sense of guilt, which in turn can enhance prosocial attitudes (Hoffman, 2000).

Empathy is important in reducing aggression, propensity for crime, and bullying (Davis, 1996). There is substantial evidence for the association of antisocial behavior with low empathy (Jolliffe & Farrington, 2004) and a weak, negative correlation between general empathic predisposition and violent behavior (Ahmed & Braithwaite, 2004; Correia & Dalbert, 2008; Endresen & Olweus, 2001; Jolliffe & Farrington, 2006), including in the long-term (Olweus, 1994). Triggering of empathy results in fewer aggressive responses to provocation (Richardson, Green & Lago, 1998). It has also been included in intervention programs (Chalmers & Townsend, 1990; Chandler, 1973; Twemlow, Fonagy, Sacco, Gies & Hess, 2001; Robinson & Maines, 1997), where it proved effective in promoting altruism and reducing bullying in schools. Furthermore, empathy is useful in enhancing students' communication and negotiation skills (Galinsky, Maddux, Gilin & White, 2008).

Human Mind in Cyberspace

For the empathic arousal to be triggered in the first place, another person is needed. This fact raises important issues relating to the digital sphere, in particular cyberbullying, such as: what factors stimulate it and how can it be suppressed? Further questions followed. Is empathy evoked in face-to-face contact (offline) the same as the one triggered by the medium of the Internet? Can the effects of its activation, such as inhibition of violence and aggression observed in research on offline behavior be generalized to cyberspace?

In his seminal work, *Understanding Media*, McLuhan (1964) pointed out that from a long-term perspective the communication of messages proved to be less important than the medium itself and the way it affects our thoughts and actions. More recent findings have also confirmed the insights of two great psychologists, Freud and James, who marvelled at the incredible property of the human brain, particularly its plasticity. Plasticity means that our brains are constantly changing in response to our experience and behavior, reorganizing neural circuits. The hitherto functioning circuits are constantly changing with every stimulus received, every movement, reward signal, action plan, or any change in our consciousness (Pascual-Leone et al., 2005). The way we think, perceive, and act, rather than being determined entirely by our genetic makeup and experience, changes under the influence of the tools we use (Carr, 2010).

Popularization of the print media, followed by the Internet, has transformed the way we read. Specific areas of the brain have been developed that specialize in quick text recognition. They are designed to represent important visual, phonologic, and semantic information, and seek them out with an incredible speed. As a result, the brain can easily decode text and can devote more resources to its understanding and interpretation. These neurophysiological changes in the process of reading have freed up readers' intellectual abilities (Carr, 2010).

Similarly, frequent use of tools offered by the Internet (e.g., browsers) results in new changes at the neurological level. Distinct new neural pathways are also formed (Small & Vorgan, 2008). Reading online is said to be different from traditional print. The former, focused on decoding, limits the ability to form numerous connections, while the latter invites more in-depth reading. Thus, our potential to make multiple connections (formed with in-depth reading)

remains largely unexploited with online browsing. A more direct case of neural and psychological differences between online and offline modes relates to the reduction of aggression. Daniel Goleman (2006) noted a principal incompatibility between the "wiring" of the parts of our brains responsible for our social contacts and the interface used in online interactions. The way we communicate online may confuse our brains' social centers located in the prefrontal cortex. These circuits are constantly and automatically monitoring both the behavior of the subject and the other person during real interactions in order to eliminate interference and inhibit hostile, inappropriate, or dangerous behavioral impulses. To operate efficiently, this mechanism requires real-time feedback from the partner of the interaction. The Internet, however, does not allow for the exchange of that information to occur (in contrast to other audio-visual channels). The brain circuits responsible for inhibition become "confused," due to the lack of feedback from the other person. This leads to disinhibition (unchecked impulsiveness), usually associated with intensely negative states.

The phenomenon of disinhibition widely known since the advent of the Internet, is manifested in the form of "flaming," i.e., the tendency to post offensive messages. Cyber-disinhibition appears to be particularly perilous for young people as the circuits responsible for inhibition do not fully mature until 20 years of age. The result is a basic developmental mismatch between a poorly developed impulse inhibition and fully matured emotional impulsiveness. One of the symptoms of this developmental gap in adolescents is cyberbullying.

Empathy on-line. Can empathy activated online successfully decrease cyberbystander reinforcing cyberbullying behavior? There are empirical data that confirm its beneficial consequences in online context (Machácková et al., 2013).

From the perspective of the present study, the results of a broad online, experimental research program simulating computer-mediated communication as particularly interesting (Barlińska, Szuster & Winiewski, 2013; Barlińska & Szuster, 2014; Barlińska, Szuster & Winiewski, 2015). One of its main goals was to test the influence of situationally activated affective and cognitive empathy on the behavior of bystanders to cyberbullying by measuring the frequency of forwarding messages containing information embarrassing to a peer. The method for activating empathy followed dozens of offline studies. In order to activate affective empathy, a 2-minute video recording presenting a story of a cyberbullying victim was used.

The video presented the course of the event, the feelings of the victim, and the consequences. In order to activate cognitive empathy, the same video with the induction task was used. Participants were instructed to identify with the situation depicted in the video, and then to select from the list of characteristics those which reflect the emotions or behavior of the victim by checking the relevant boxes. The results have shown that the arousal of both affective and cognitive empathy is an effective method of limiting behavior reinforcing cyberbullying in adolescents. Exposure to the suffering of another person (affective empathy) as well as activation of perspective taking by focusing on emotions and actions of the victim (cognitive empathy) significantly decreased the frequency of forwarding a message with information embarrassing to the victim.

In Search of a Simple Method: Description of Research

In most of the studies aimed at activating empathy (including on-line research), prepare purposefully-made materials in the form of more or less complex narratives or images

presenting a number of complex stimuli suggesting the discomfort of the person depicted. This method amounts to a direct transfer of the offline methods to cyberspace. As demonstrated by empirical findings, it proved to be effective in activating empathy in order to inhibit cyberbystander reinforcing cyberbullying behavior. However, its viability as an online tool may be limited as it requires focus and concentration, not only to decode, but also to integrate and interpret the cues presented. Thus, it is more-time consuming. A method that is effective in a laboratory setting (simulating an online contact) may not prove to be equally efficient in actual online reality.

The challenge is to develop an empathy-triggering method appropriate for the cyberspace context. The specifics of “stimulus decoding on the Internet” dominated by the activation of circuits responsible for decoding rather than deep processing,

The purpose of the present research was to investigate responses to human faces as a method for inhibiting support for cyberbullying. The face is a unique, universal social stimulus. Its special status is confirmed by the existence of an independent neural system that processes facial information. Considering our innate ability to decode facial expressions of basic emotions (including the subliminally presented ones - Murphy & Zajonc, 1993), and their effects on evaluation processes, it seems reasonable to use them in research on curbing cyberbystander reinforcing cyberbullying behavior.

The research using Magnetic Resonance Imaging shows that mere exposure to facial expressions of various emotions resulted in increased arousal in the parts of the observer’s brains which were involved in producing those expressions (Carr et al., 2003). Based on those findings, Preston and De Waal (2002) proposed a perception-action model of empathy, according to which both the observation of and imagining what another person feels automatically triggers the neural pathways responsible for representing the affective states of the observed person. With these mental representations it is possible to recognize others’ emotions and express them. The existence of common affective neural pathways may explain how other people’s emotions can be experienced by us as our own.

Other studies on neural mechanisms underlying empathy have shown that the exposure to the face expressing sadness or pain is enough to activate mirror neurons which once presented with a more complex situation involving another person’s needs are also responsible for empathy arousal (De Vignemont & Singer, 2006). This suggests two forms of evidence for the effectiveness of empathy activated by the exposition of a single stimulus - a sad face. The first is that the presentation of a face with a facial expression alone activates the same areas in the observer, and the second that these areas are also involved when more complex situations associated with discomfort are dealt with. We can assume that the affective mirroring can also explain the effectiveness of exposure to a sad face as an empathy-triggering stimulus. It was, therefore, expected that exposure to a face expressing sadness would significantly decrease support for cyberbullying behavior. Another question was what effects will be achieved in comparison to empathy activation with the use of complex stimuli.

METHOD

A study of an experimental character was conducted using a web application created for the purpose of the study. It simulated a popular online communication tools among teenagers, a community service, and a messaging service. Independent variables were the activation of

empathy (specific vs. non-specific for a given situation), experiences as a perpetrator of cyberbullying, and gender. The dependent variable was a cyberbystander's choice between neutral or cyberbystander reinforcing cyberbullying behavior.

Participants

Participants were junior high school students ($N = 292$, comprising 177 boys and 115 girls) from three polish districts. All students were between the ages of 11-17.

Procedures

Before participants were enrolled in the study, the consent of the headmaster, parents, and pupils was obtained. The study was anonymous and conducted in groups and on school premises. In order to control the access to the website, each participant logged in using a unique, one-time password. The first task was different for particular groups. In the first group students were shown the pictures of sad faces (I), in the second group participants watched a two-minute film (the story of a victim of cyberbullying) (II), and the control group viewed no expositions (III). Students were randomly assigned to control and experimental groups. Then, the participants in all groups received the second task "Message from a friend".

After reading the message, they were asked to choose how to act: send vs delete (see Table 1). Next, they completed a questionnaire to measure the severity of the experience of cyberbullying. At the end of the study, students, teachers, and parents were provided with general feedback.

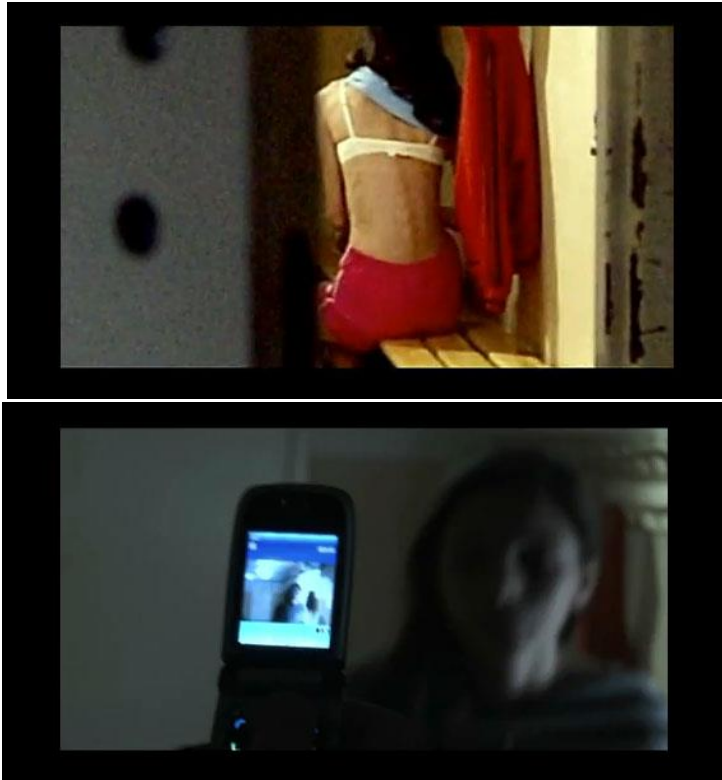

Table 1. Study design I - conditions and indicators

Study conditions	Behavior of a cyberbystander		Experiences as a perpetrator of cyberbullying
	Cyberbullying reinforcing behavior	Neutral behavior	
Activation of non-specific empathy	Send	Delete	
Activation of empathy (specific for a given situation)			
Control group			

Measures

"Film." In order to activate empathy (specific for the cyberbullying situation) a two-minute film was shown. It presented the story of a young girl who was a victim of cyberbullying. She was filmed by a school colleague while she was dressing for P.E. in a locker room. The film showed the course of events and consequences by presenting a cyberbullying victim's behavior. It also included a statement expressing her feelings and experiences. The video was posted on the web and gradually gained popularity so she became a figure of fun. She experienced strong negative feelings and emotions like shame, humiliation, ridicule and fear. This situation also had an impact on her behavior: isolation from contemporaries, not going out (from home), and school absenteeism.

Screenshots from the film are presented below:

“Faces.” In order to activate non-specific (for a cyberbullying situation) empathy, an online platform task was prepared. Each participant was shown 14 faces which expressed sadness (6 male and 8 female faces). Photos came from the Pictures of Facial Affect (POFA) set made by Ekman and Friesen (1976). The facade task assigned to the adolescents during the expositions was to determine whether they like the presented faces or not. After selecting one of the two options, another photography appeared.

Screenshot from the “faces” tool is presented below:

“Message from a friend.” In order to introduce interaction in the task, a web application was used. A “Message from a friend” tool was created, with its main element in the form of a picture presented as a message from “a peer.” It contained a manipulated debasing image showing a boy’s face on the body of a dog with the following comment: “Hi, this is my classmate, he looks like a total fool.” The situation was inspired by some cases reported to the helpline.org.pl website which as part of the Safer Internet project that provides support to the victims of Internet threats. In order to activate the online interaction setting, the “Message from a friend” was provided via a web application similar to a text messenger which was a part of the purpose-made online community. Participants were asked to choose one way of acting by either selecting “send” to a friend on the messaging service (cyberbystander reinforcing cyberbullying behavior) or “delete” (neutral behavior).

Screenshot of the application is presented below:

Cyberbullying questionnaire. A questionnaire of the cyberbullying experience (Barlińska & Wojtasik, 2008) was employed. It consisted of two parts, one for cybervictimization and the other for cyberperpetration. The cyberperpetration subscale was used for this research. It contained five questions related to this kind of experience, for example: "Have you ever posted or sent material that was false or embarrassed someone?" Responses were indicated on the 5-point Likert-type scale (1 = *never* to 5 = *several times*). It proved to be internally consistent, $\alpha = .74$ (M perpetrator = 1.74, $SD = .68$). The scores were used in further analyses.

Plan of Analysis

Logistic regression analyses were conducted in order to evaluate whether empathy reduces the likelihood of such cyberbystander behavior that reinforces cyberbullying. Additionally, it was considered whether the previous experiences as a perpetrator of cyberbullying influenced the frequency of choosing the above mentioned kind of behavior, and what impact gender had on the violence enhancing actions.

RESULTS

A little over 15.4% ($n = 45$) of the sample selected a behavior that reinforced cyberbullying. A logistic regression analysis was conducted, with selected behavior (0 = neutral: 1 = cyberbullying reinforcing behavior) as the dependent variable (see Table 1). Table 2 presents the figures of the odds ratio coefficients with 95% confidence intervals, Wald statistic with the level of significance for each variable at each stage of the analysis, overall model match statistics, and the selected detailed parameters. The model suggested a good match (Likelihood ratio test = 95.98; score test = 21.97) and reasonably good predictive abilities (Cox & Snell $R^2 = .08$; Nagelkerke $R^2 = .14$).

On the basis of the obtained relevant odds ratio coefficients, it can be concluded that the probability of a cyberviolence enhancing behavior of a cyberbystander in the activation of empathy conditions (the film presentation) is considerably lower than in the control conditions (odds ratio coefficient $OR = .31$). Similarly, the activation of non-specific empathy (face images) decreases the probability of a cyberbullying reinforcing behavior of a bystander (odds ratio coefficient $OR = .20$). On the basis of the obtained relevant odds ratio coefficients it can be concluded that the probability of a cyberbullying reinforcing behavior of a bystander increases with the intensity of the experiences of the Internet violence perpetrators (the odds ratio coefficient, $OR = 1.40$).

The influence of gender was insignificant. The analysis of frequency revealed that in the experimental conditions I (non-specific empathy activation) 14.3 % ($n = 14$) of the participants chose a cyberbullying reinforcing behavior, in the experimental conditions II (activation of empathy specific for given situation – film) 8.2 % ($n = 8$) chose this behavior, and 23.7% ($n = 23$) in the control group chose likewise.

Table 2. The results of the logistic regression analysis for the activation of empathy (specific vs. non-specific for a given situation)

Predictor	B	SE β	Wald's χ^2	Df	p	OR (95% CI)
Experimental conditions			11.77	2	.003	
Act. of empathy (Faces)	-1.61	.60	7.70	1	.007	.200
Act. of empathy (Film)	-1.16	.44	0.22	1	.009	.314
Exp. cyber perpetrator	.34	.10	3.99	1	.001	.402
Gender (1 = girls)	-.34	.38	5.41	1	.362	.710
TEST	χ^2		Df		P	
Overall model evaluation						
Likelihood ratio test	95.983		1		.001	
Score test	21.97		4		.001	
Goodness-of-fit test						
Hosmer & Lemeshow	8.61		7		.282	
Cox & Snell $R^2 = 0,08$; Nagelkerke $R^2 = 0,14$.						

The results show a strong impact of previous experiences as a cyberperpetrator on reinforcing cyberbullying as a cyberbystander. These findings are consistent with previous studies (Barlińska, Szuster & Winiewski, 2013; Barlińska & Szuster, 2014; Barlińska, Szuster & Winiewski, 2015). Additionally, there is a substantial effect of the experimental conditions (film vs exposition of sad faces) which significantly decreased the frequency of a cyberbullying reinforcing behavior of a cyberbystander.

Figure 1. Cyberbullying reinforcing behavior of a cyberbystander in various conditions.

DISCUSSION

The results of the presented study indicated that empathy is activated not only by a complex stimulus. Also a mere exposure of a face significantly limits cyberbystander reinforcing bullying behavior. Furthermore, the results suggested that gender does not affect a cyberbystander's behavior, which is consistent with the results of other research (Ball, 2007; Li, 2006).

The obtained findings, which indicated empathy as an effective protective factor, have proved to be in line with different data referring to the relationship between empathy and cyberbullying, especially with data stating that children in probullying roles seem to lack empathic understanding of victims (Salmivalli, 2010). On the other hand, withdrawal from and staying away from bullying situations is positively associated with empathy (Gini, Albiero, Benelli & Altoe, 2008; Salmivalli, 2010), which was also confirmed by the presented study.

Our results are coherent and consistent with the findings of other studies focused on the role of empathy (Hoffman, 2000) and perspective taking (Clore & Jeffrey, 1972), which confirms their validity. The findings also extend the current knowledge on the associations between cyberbullying and empathy by showing that the situational activation of empathy may also limit behavior supporting online aggression. Empathy, being the most natural aggression inhibitor for adolescents, plays a significant role in preventing the negative bystander behavior that supports cyberbullying. The ability to "mentalize," underlying this behavior modification (Frith & Frith, 2003), is a unique characteristic of the cognitive aspect of empathetic responses. It encourages a deeper understanding of the other person's circumstances while, at the same time, preventing pro-cyberbullying activities.

It appears noteworthy to understand the results in the perspective of empathy activating processes. In the second condition, empathy was aroused through the use of material directly corresponding with cyber-violence. Therefore, the considerable reduction of behaviors supporting the on-line harming of others in the second task is not surprising. In the first condition, a face with an expression of sadness was exposed. So, the stimulus contents did not directly refer to the context of cyber-violence. Notwithstanding, it turned out to be similarly effective in reducing the supporting of cyber-violence perpetuating behavior of cyberbystanders. Arguably, the film activating the contents corresponding with the context of cyber-violence increased accessibility of the victim's perspective and, consequently, curbed the behaviors supporting discomfort of others. The change was also of analogous nature. The exposure of face had a non-analogous impact in the sense that it was not directly related to the contents of the stimulus. It may well be presumed that a human face acts more like an automatic filter that increases mindfulness and focuses attention. This is also confirmed by the unique character of this stimulus which is an object of a most universal meaning. Doubtlessly, validity of such interpretation requires further research that should in turn make use of subliminal exposures of a human face.

Several specific implications for the prevention of cyberbullying behaviour naturally follow from the results of this study. Online aggression can be reduced by empathy activation. Despite its effectiveness, limitations due to the strength of the effect and exposition of one's appearance online can be reduced, although its effectiveness in limiting cyberbystander reinforcing bullying behavior shall be maintained. Empathy activated in this way can prevent uncontrolled cyberbullying acts, which may lead to some consequences. First, it may limit the

victimization impact as the cyberbullying act is less experienced by the victim (Smith, 2011). Second, if fewer children reinforce the bully an important reward and motivation for bullying others would be lost and finally the bullying may likely be stopped (Salmivalli, 2010). A program devoted to a consequent empathy activation can play an important part in reducing online bullying.

The vast majority of both types of bullying acts are carried out in the presence of the audience (Barlińska, Szuster & Winiewski, 2013; Barlińska, Szuster & Winiewski, 2015; Craig & Pepler, 1997; Craig, Pepler & Atlas, 2000; O'Connell, Pepler & Craig, 1999); Salmivalli, 2010). However, this presence is different depending on the type of environment – offline *versus* online. Because of computer-mediated communication the online presence of a bystander generates a very specific form of appearance and yields certain consequences. Appearance is the leading cause of concern for adolescents. Research on body dissatisfaction clearly shows that a sort of imbalance in a person's self-concept has a negative impact both on his or her personal wellbeing as well as social relationships (Rumsey & Harcourt, 2012). An analogous imbalance is created by cyberspace characteristics. Computer-mediated communication, with its reduced social and contextual cues, lacks affective feedback (Kiesler, Siegel & McGuire, 1984). Online human presence is schematic and devoid of emotional signals which creates a paradox. On the one hand, it causes absence of restraints in social behavior typical of direct interaction (Suler, 2004).

It creates distinctive conditions that encourage unwitting aggression reinforcing cyberbullying. On the other hand, it generates the need for self-exposure and disinhibited self-presentation while diminishing the sense of responsibility (McKenna, 2008). In such contexts, devoid of emotional signals, empathy activation using the human appearance, such as the face seems to meet this is need. At the same time, it may help adolescents to develop aggression free online relationships.

CONCLUSION

The word "method" used in the title evokes two meanings of the term. The one that comes immediately to mind denotes the method that can be used in the prevention of cyberbullying. The second has certain philosophical connotations. It refers to universal methods used in the pursuit of truth. Although Descartes recognized the importance of reasoning, he was not fully aware of the traps the minds sets up. He could hardly sense how significant the tools of our perception are for the way we see reality. They determine its contents. It was with the advent of computers and the Internet that we have come to recognize the full extent of that mechanism. Does our mind process and respond to the face presented by the medium of the Internet? Are the methods used by our minds changing with the tools we use? Probably. Our online activities are dominated by superficial, non-linear processing of stimuli, increased eye saccades, and scanning. However, even in these circumstances, the human face appears to be a salient enough stimulus that its processing remains unaltered.

Our findings may be the starting point for further research aimed at developing new and improving existing methods of triggering empathy, which proved successful in reducing negative behavior in cyberspace. The main objective of future research should be to better adapt methods for arousing empathy (and, in future, such other aspects as self-control and social norms) to the "language" of the Internet. There is no doubt that the Internet changes the way

we receive and process information, especially among adolescents, whose social functioning has been from the very beginning defined by their presence online.

It was predicted that research on the consequences of exposure to the human face in cyberspace is devoid of direct contact with another person and all its psychological outcomes. In particular, it could serve as a basis for developing new, simpler prevention methods using, in a variety of contexts, the face as a universally recognizable stimulus eliciting universal responses. Planned placement on the Internet would enrich available prophylaxis.

Chapter 22

AN ANALYSIS OF CYBERBULLYING VICTIMIZATION CASE STUDIES IN THE CONTEXT OF THE SOCIAL- ECOLOGICAL THEORY

William Stanley Pendergrass^{1,*} and Michelle F. Wright²

¹American Public University, WV, US

²Masaryk University, Brno, Czechia

INTRODUCTION

Nowadays adolescents are fully immersed in electronic technologies. There is a dark side to their usage of these technologies: Cyberbullying. Cyberbullying is an extension of traditional bullying and it involves bullying behaviors using electronic technologies, such as email, instant messaging, Facebook, and text messaging through mobile devices. The ability to remain anonymous is one potential factor contributing to adolescents' involvement in cyberbullying. This chapter begins by defining bullying and cyberbullying as well as describing the victims of cyberbullying. Next, we review various case studies involving victims of cyberbullying by describing the situations leading up to the cyberbullying and the cyberbullying incidence. The chapter concludes by applying the social-ecological theory to each of these cases in order to highlight how multiple individuals are directly and indirectly involved in cyberbullying.

DEFINITIONS OF BULLYING AND CYBERBULLYING

Olweus (1994) introduced the current definition of bullying. In order for an act to be considered bullying, it needs to meet three criteria: (a) the act must be intentional, (b) the act must be based on an imbalance of power, and (c) the act must be repeated (Levy, Cortesi, Gasser, Crowley, Beaton, Casey & Nolan, 2012; Olweus, 1994). Intentionality is differentiated from random or accidental actions which could also harm someone; the behavior needs to be

* Corresponding Author's Email: william.pendergrass@mycampus.apus.edu.

purposeful. An imbalance of power accentuates the differences between victims and perpetrators in regard to not only the perpetrators' physical strength, but of their social position in relation to the victim, including intelligence or popularity. Finally, repetition means that the harmful intentional actions reoccur over a period of time. Cyberbullying is bullying, using the above definition, but it involves information and communication technologies (ICTs) or other types of Internet technologies. Using these definitions, lawmakers are increasingly viewing cyberbullying as a legitimate and dangerous form of harassment which requires legislative remedy (Feldsher, 2015).

CYBERBULLYING GOES MOBILE

Because of the relatively recent rise of both the availability of cellular communication devices, the explosion of capabilities these devices can offer, and the decreasing cost of obtaining and maintaining said devices, the majority of parents have purchased these devices for all members of the family. These devices have quickly become not only the primary means of conversation but they have also helped define social standing in the children's world. After the introduction of smart phones, services such as texting have been joined by social media such as Facebook, Twitter, Instagram and Vine. These services allow for the free flow of communication between individuals. In addition, conversation applications such as Ask.fm, Kik, Yik Yak, Whisper, Secret, and Voxel allow users to post anonymously or through a username, often creating a perfect avenue for cyberbullies (Alvarez, 2013). Additionally, more and more anonymous apps are being created and introduced each year. (Alsapach, 2015; Perez, 2015) This increasingly puts parents and school administrators at a disadvantage because they are always playing catch up to the next new thing.

WHO ARE THE CYBERBULLIED?

Cyberbullying is not location dependent; however it may be device dependent. In particular, cyberbullying can occur through electronically-mediated communication at school and outside of school as well (Tokunaga, 2010). Cyberbullying also is dependent on the social groups which are involved. What behaviors an adult might consider cyberbullying, some teenagers might see only as "Drama" (boyd, 2014). Drama is define as social and interpersonal, involving relational conflict that is often reciprocal and gendered (Marwick & boyd, 2011). It might also be magnified by networked publics. Teenagers between the ages of 12 to 14 appear to be the most vulnerable to cyberbullying victimization (Tokunaga, 2010). This coincides with the ages of those vulnerable to offline bullying. Cyberbullying is more prevalent in middle school than high school and is most likely to occur when starting middle school or starting at a new school (Espelage & Horne, 2008).

Victims of cyberbullying generally report that they feel more dependent on the Internet, and they usually take more Internet-related risks, such as meeting online strangers offline in person (Vandebosch & Van Cleemput, 2009). Many cyber victims are rejected by and do not get along with their peers (Wright & Li, 2013). They also have problems concerning emotional

closeness with their parents (Katzer, Fetchenhauer & Belschak, 2009). Many victims are also likely to engage in unusual behaviors, daydreaming, and impulsivity.

Cyberbullying victimization relates to offline problem behaviors, such as the use of alcohol, skipping school without an excuse, and cheating on a test (Hinduja & Patchin, 2007). Additionally, victims also experience anxiety, depression, and negative self-image (Katzer, et al. 2009; Schultze-Krumbholz & Scheithauer, 2009). Many times, cyber victims fear for their safety at school, and have academic achievement problems (Wright, 2015; Ybarra & Mitchel, 2004).

PRESENT STUDY AND METHODS

Data on cyberbullying victims was collected from secondary sources using a variety of means as part of a larger study on hackers, hacktivists, and cyber security issues. Most of the information came from electronic news sources which were collected each day through the use of Google Search terms. Search terms related to this paper's development included cyber, cyberbullying, Anonymous, hacktivist, and hackers. This data formed the bulk of the material collected; however, other sources of information were also used when applicable. These other sources included items, such as print newspapers, print magazines, radio and television broadcasts, and motion picture documentaries. Each week the Google Search term feeds were reviewed and applicable articles were binned into appropriate categories which included cyberbullying in general, specific cases of cyberbullying, and hacktivists' responses to cyberbullying cases. Over time, this amounted to several hundred document sources on several cyberbullying events with thousands of pages of actual reported information.

In order to condense such a huge amount of raw information and consolidate it into a coherent story, the case study method of research was utilized. Yin (2009) described two criteria for using this method. First, a case study methodology is useful in order to understand a real-life phenomenon in depth, and secondly, a case study handles technically distinctive situations where there are many more variables of interest than data points and multiple sources of evidence. Yin defined three principles of data collection, including using multiple sources of evidence, creating a database of these sources, and maintaining a chain of evidence. Using these criterial and principles, an analysis of the binned categories of sequentially sorted articles was conducted to identify trends, themes, issues, and results. The result of that analysis follows. Later, the cyberbullying victimization cases are analyzed in relation to the social-ecological theory. The social-ecological theory has been used as a framework to understand bullying (Espelage, 2014). Therefore, the theory suggests that bullying and victimization are outcomes of interactions between individuals and their environments. The theory can also be used as a foundation for understanding cyberbullying. According to the theory, cyberbullying might occur because of the interaction among individual characteristics (e.g., age, gender, personality) and various systems, including the microsystem (e.g., family, peers, schools), mesosystem (interaction between microsystems), exosystem (e.g., mass media, neighbors, industry), and macrosystem (e.g., ideologies of the culture).

The purpose of applying this theory to these cases of cyberbullying victimization is to provide an understanding of cyberbullying as a phenomenon affecting youths themselves but also their families, schools and teachers, and communities.

RECENT CASES OF CYBERBULLYING VICTIMS

Audrie Pott

Audrie Pott, a fifteen-year-old Sophomore at Saratoga High School in Silicon Valley, California, hung herself in her bathroom and died on September 10, 2012 (Stebner, 2013). Just the week before, Audrie and a friend told her parents that they wanted to have a sleepover at the friend's house. After being dropped off, Audrie and her friend went to another friend's house where a party was underway. At the party, there were eleven teens downing shots of vodka, rum, and tequila. Audrie was making out with one boy then passed out and was taken upstairs to a bedroom by three male friends and a female teen. The girl left Audrie alone with the boys when they started to remove her clothes and draw on her body with Sharpies.

In interviews with police later, [the boys] admitted, to varying degrees, coloring half of [Audrie's] face black, then pulling down her bra, taking off her shorts and drawing scribbles, lines and circles on her breasts and nipples. [One of the boys] wrote "anal" above her ass with an arrow pointing down. At some point [later, the girl] returned to find Audrie in her underwear and put a blanket over her, then left the room again. With Audrie still sprawled out on the bed and unresponsive, the boys allegedly fingered her and took pictures on their phones (Burleigh, 2013).

The next morning, Audrie woke up disoriented and scared, her body covered in green and black ink which she frantically tried to scrub off her skin. She called her mother to come pick her up. Over the next few days Audrie tried to piece together what had happened from friends and classmates. She quickly realized that the entire school might have seen the pictures and videos.

In conversations on Facebook, "Audrie wrote that the 'whole school knows. . . Do you know how people view me now? I fucked up and I can't do anything to fix it. . . And I now have a reputation I can never get rid of. . . My life is over. . . I ruined my life and I don't even remember how'" (Burleigh, 2013). Audrie left no suicide note, gave no warning of her pain and her plan, after her mother picked her up from school and they returned home, Audrie locked herself in the bathroom and hung herself with a belt from the shower head. Her mother found her 20 minutes later, her face stained by the mascara that ran down her face. After calling 911 she attempted CPR, awaiting the paramedics' arrival. When they arrived, they could not revive her (Burleigh, 2013). After an investigation into the case, on April 11, 2013, the three teen boys who assaulted Audrie were finally arrested for sexual battery against her (Dahl, 2013).

Amanda Todd

Fifteen-year-old Amanda Todd hung herself in her Port Coquitlam, British Columbia, Canada home at 6 p.m. Wednesday, October 10, 2012, one month before her 16th birthday and just five weeks after she posted a heartbreaking video on YouTube which detailed how she was harassed and bullied online. The video is titled "My Story: Struggling, bullying, suicide and self-harm" (Dufour, 2012; Shaw & Culbert, 2012). The video shows Amanda telling her story of cyberbullying and harassment through flash cards.

When Amanda was in 7th Grade, in an online video conversation with an unknown man, after being bated with lavish praise telling her how beautiful she was, she was asked to flash her breasts; unfortunately, she did. The person had recorded the conversation and now had a screenshot of that moment. A year later, she was contacted by the man through Facebook. He threatened that if she didn't put on another show for him, he would send the photo of the screenshot to her family, friends, and schoolmates. He had all her personal information: Facebook profile, address, school name, names of family members, names of friends, etc. She refused to do it. Over Christmas Break, the police showed up at her door at 4 a.m. with a photo of the screenshot in hand asking if she had forwarded it. Apparently, the photo had been sent out to all her family and friends just as the man had threatened. As a result, she grew depressed and anxious, turning to alcohol and drugs in order to try to cope (Thesomebodytoknow, 2012).

Amanda ended up switching schools, but the cyberbullying followed her. The man who had threatened her, created a Facebook page of her with the picture of Amanda's breasts as his profile picture. Her schoolmates began to turn on her; they made fun of her and picked on her, calling her names. She started to cut herself. She was moved to yet another school where she made friends with a boy who told her that he liked her. While the boy already had a girlfriend, one day he confided that his girlfriend was on vacation and that she should come over to see him; they had sex. A week later, Amanda was confronted by the girlfriend, the boy, and a large group of teens in front of her school and beaten up by the girl. The attack was filmed; she was left beaten up in a ditch. Amanda's father came to pick her up afterwards to take her home. Despondent, Amanda tried to kill herself by drinking bleach. She was rushed to the hospital and survived (Thesomebodytoknow, 2012).

After her suicide attempt, many of her Facebook friends posted cruel comments about how she deserved it, asking if she got the mud out of her hair with the bleach and adding that they hoped she was dead. She moved in with her mother in a new city and a new school and she thought things might get better, but her tormenters followed. Comments on her Facebook page continued to taunt her toward suicide. Photos of bleach bottles and ditches were tagged with her profile. Now she rarely left the house; she was prescribed antidepressants and started counseling. After an overdose which required a two day stay in the hospital, she decided to make the video of her experience with bullying (Thesomebodytoknow, 2012).

The YouTube page included the following introduction which she penned:

I'm struggling to stay in this world, because everything just touches me so deeply. I'm not doing this for attention. I'm doing this to be an inspiration and to show that I can be strong. I did things to myself to make pain go away, because I'd rather hurt myself then [sic] someone else. Haters are haters but please don't hate, although im [sic] sure I'll get them. I hope I can show you guys that everyone has a story, and everyones [sic] future will be bright one day, you just gotta [sic] pull through. I'm still here aren't I? - Amanda Todd (2012) (Thesomebodytoknow, 2012).

Jessica Laney

On December 9, 2012, Jessica Laney, a sixteen-year-old Fivay High School student from Hudson, Florida, hung herself. Friends told authorities investigating the suicide that she had been cyberbullied through the Latvian-based question and answer website, Ask.fm (Murray, 2012; Roberts, 2012). While Laney's ask.fm account page, Jessicamariee1, had a fair share of

innocent comments about which boys in school she liked and people telling her how pretty she was, there were also a number of posts attacking her, telling her she was fat and a loser.

"Classmates... say she was pretty and bubbly. Still, cruel comments could be found on her Ask.fm webpage. "Nobody even cares about you," reads one anonymous post. "Can you just kill yourself," says another. Close friends, Cheyenne Ellsmore and Lisa Arthur, say people would post the mean messages anonymously. "You get compliments sometimes but it's those negative comments that bring you down," Ellsmore said. "There's just things you should say and things you shouldn't," said Arthur. "And on Ask.fm, none of that should be said." The girls believe the comments got to be too much for Laney, who took her own life Sunday night." (McVey, 2012)

Jessica had transferred to Fivay High School because of bullying at her previous school. A friend of Jessica, Valerie Canales, wrote on Jessica's Facebook tribute page, which was established after her death, that the abuse that she received on Ask.fm was what pushed her to take her own life.

"...last night, my friend Jessica Laney took her life. She was constantly bullied and bullied. And she was pushed and pushed to the point where she couldn't handle it anymore. And if you could spread the word about the website ask.fm & how it needs to be shut down, that would be amazing too. Ask.fm is a website where people can ask anonymous questions to anyone they want. And that's [sic] how Jessica was constantly put down and bullied. She was a beautiful girl & everyone loved her. She's [sic] gonna [sic] be missed. We have to put an end to bullying. Please help..." (Roberts, 2012)

Rehtaeh Parsons

Rehtaeh Parsons, a seventeen-year-old Cole Harbour District High School student, attempted suicide by hanging on April 4, 2013, at her home in Dartmouth, Nova Scotia, Canada. She did not succeed which led to her falling into a coma. On April 7, 2013, her family made the decision to remove her from life support; she died the same day (The Huffington Post, 2013). In November of 2011, Rehtaeh was at a small gathering of friends when she was photographed while having sex with one of the boys. Her mother, Leah Parsons, described the events of the night and the subsequent abuse on a Facebook memorial page dedicated to Rehtaeh:

The person Rehtaeh once was all changed one dreaded night in November 2011. She went with a friend to another's home. In that home she was raped by four young boys . . . one of those boys took a photo of her being raped and decided it would be fun to distribute the photo to everyone in Rehtaeh's school and community where it quickly went viral. Because the boys already had a 'slut' story, the victim of the rape, Rehtaeh, was considered a slut. This day changed the lives of our family forever (Visser, 2013).

The cyberbullying and harassment against Rehtaeh continued unabated. Her mother said, "She was never left alone. She had to leave the community. Her friends turned against her. People harassed her. Boys she didn't know started texting her and Facebooking her asking her to have sex with them. It just never stopped" (The Huffington Post, 2013). The family moved

to nearby Halifax but the harassment did not stop. As a result, Rehtaeh began to suffer from depression and anger and at one time had to be admitted to a hospital on fears that she would harm herself. A yearlong investigation by the Royal Canadian Mounted Police (RCMP) concluded that there was not enough evidence to charge and convict any of the boys with rape. Shortly after her death in April, members of the hactivist group, Anonymous, threatened to release the identity documents or dox of the boys involved unless the RCMP brought about charges (Visser & Cross, 2013). Initially, upon Rehtaeh's family's request, the boys' names and identities were not released (CBC News, 2013).

Ultimately, the attention and pressure brought by Anonymous helped to persuade other witnesses to come forward with new information. This convinced the RCMP to reopen the investigation on April 11, 2013 (Prentiss, 2013). In July, citing inactivity by the RCMP, Anonymous made the names of the boys public. (Morris, 2013a) Finally, in August of 2013, two of the teens involved were arrested and charged with child pornography, but not with rape. The RCMP commented, "What some people may believe occurred and what can be substantiated in a police investigation through verified evidence and what can finally be proved in court are often very different things. We, as police officers, cannot act on innuendo or speculation. We do not cultivate facts. We verify them" (Morris, 2013b).

Rebecca Ann Sedwick

On September 9, 2013, Rebecca Ann Sedwick, a twelve-year-old Crystal Lake Middle School student, jumped to her death from a tower at an abandoned concrete plant less than one mile from her home in Lakeland, Florida. She had been the victim of cyberbullying for months. Rebecca was reported missing about 7 p.m. that Monday by her mother after she failed to return home from school. Authorities later learned she left her home without her school books that morning and never boarded her school bus (Stennett, 2013). After an investigation, two girls from her school were eventually arrested. They were part of a group of 15 girls who were accused of tormenting Rebecca. The arrests came after one of the two girls tweeted, "Yes IK [I know] I bullied REBECCA nd [sic] she killed her self [sic] but IDGAF [I don't give a fuck]" (Quigley & Gorman, 2013). The torment began after one of the girls began dating a boy Rebecca had dated earlier and she didn't like that Rebecca and the boy remained friends. That girl even turned the other girl who was also arrested, formerly a good friend of Rebecca's, against Rebecca.

Witnesses told investigators she sent messages to Rebecca, calling her ugly, telling her to "drink bleach and die," and encouraging her to kill herself. Rebecca's computer searches revealed she had searched for ways to commit suicide and asked questions like, "What is overweight for a 13-year-old girl." One of the Florida girl's screensavers also showed Rebecca with her head resting on a railroad track. [Rebecca] changed one of her online screen names to "That Dead Girl." She messaged a boy: "I'm jumping." Polk County Sheriff Judd said Rebecca had been "absolutely terrorized" by the other girls. "We can see from what we've been investigating so far that Rebecca wasn't attacking back," Judd said. "She appeared to be beat down. She appeared to have a defeatist attitude. And quite frankly, the entire investigation is exceptionally disturbing" (Quigley & Gorman, 2013).

Even when her mother took Rebecca out of school, the bullying continued online. Rebecca's mother deleted her Facebook account, but kept finding other social apps that she had downloaded to her phone where the cyberbullying still continued. In December of 2012, Rebecca was hospitalized for three days after slicing her wrists saying that it was because of the bullying.

"She put on a perfect, happy face. She never told me," [said her mother, Tricia Norman]. "I never had a clue. I mean, she told me last year when she was being bullied, but not this year, and I have no idea why." Once police checked [Rebecca's] cell phone they discovered that the bullying had not stopped, especially on Kik Messenger, Instagram and Ask.fm. "They would tell her she's ugly, stupid, nobody liked her, go kill herself," Ms Norman said (Quigley & Gorman, 2013).

The two teen girls who were arrested were released and eventually charges were dropped for lack of evidence, however, Rebecca's mother filed wrongful death lawsuits in the civil court. She also began to petition the State of Florida to enact tougher anti-bullying laws (Kemp, 2013).

CONCLUSION

A major purpose of this chapter was to review case studies of cyberbullying victims, with specific focus on the events related to the cyberbullying incidences and the outcomes. Another goal was to connect these case studies to the social-ecological perspective by examining how multiple systems were influenced by cyberbullying victimization. Each of the case studies involved peers (the microsystem) as well as the interaction between peers and schools (the mesosystem). For example, many of these case studies involved cyberbullying perpetrated by peers outside of school, with knowledge of the event "spreading" to peers at the victims' schools. Knowledge of the incidences were spread via social media (the exosystem) as well as the school environment. The involvement of the school environment for further perpetuating cyberbullying victimization indicated an interaction between peers outside of school and the school environment, representing the mesosystem, an interaction between two microsystems – in this case, schools and peers outside of school. The microsystem of family was clearly impacted by the deaths of the victims included in these case studies. Many of the families established laws and charitable foundations in the names of their children. The establishment of laws and charitable foundations involves the community, which is part of the exosystem. Establishing laws could also be considered part of the macrosystem as the hope of such laws is to alter the ideologies concerning bullying of society as a whole, which would then also become part of children's ideologies to not bully. The community was further involved in some of the cases as well. In particular, Jessica Laney's friend, Valerie Canales, appealed for her community to take action against cyberbullying by calling for "... putting an end to bullying" (Roberts, 2012). Furthermore, the victimization and suicide of Rehtaeh Parsons triggered Anonymous to take action by releasing the perpetrators' information to the community. Taken together, the case studies include the microsystem (i.e., peers, schools, families), the mesosystem (i.e., interaction between peers and schools), the exosystem (i.e., communities, laws, charitable foundations), and the macrosystem (i.e., laws). Therefore, cyberbullying

involves various systems in the victims' lives, indicating the need to understand this phenomenon as a concern for everyone, not just victims themselves.

Chapter 23

CONCLUDING REMARKS ON THE SOCIAL-ECOLOGICAL APPROACH TO UNDERSTANDING CYBERBULLYING

Michelle F. Wright*

Masaryk University, Brno, Czechia

Before putting together this book, I knew that there would be some noticeable gaps in the literature regarding investigations focused on the role of parents, peers, teachers and schools, and communities in cyberbullying. After organizing the chapters for the book, it was clear that an overwhelming amount of literature focused on individual-level predictors of cyberbullying. Given the newness of cyberbullying research, such a focus is consistent with researchers aiming to understand the risk factors and protective factors associated with this behavior in an effort to develop prevention and intervention programs.

Pendergrass and Wright (Chapter 23) suggested, after their review of cyber victimization cases studies and the application of the cases to the social-ecological approach, that cyberbullying is not just a concern for children and adolescents themselves, schools, or parents, but that everyone in our society should be involved in solutions aimed at reducing these behaviors. Therefore, it is imperative that researchers investigate the role of other context, such as parents, schools, teachers, and peers in children's and adolescents' cyberbullying involvement. Although less attention has been given to these contexts, there is a variety of research evidence that implicates their influence on cyberbullying among children and adolescents.

The noticeable gaps in the literature appear when it comes to the mesosystem, exosystem, macrosystem, and chronosystem. Based on the review of the literature, there appears to be two types of interactions among the systems. For instance, Arslan and colleagues (2012) found that parental unemployment was linked to cyberbullying. They explained that such work-related stress negatively impacted the family environment, which subsequently affected children's and adolescents' behaviors, leading to cyberbullying. Pendergrass and Wright (Chapter 23) argue

* Corresponding Author's Email: michelle.wright@mail.muni.cz.

that many of the cases involving cyberbullying victimization involved an interaction between peers and schools.

In particular, they explained that some cyberbullying incidences occur outside of school, involving neighborhood-level peers or school-related peers, “spills over” into school, further perpetuating the cycle of victimization. At the exosystem, den Hamer and Konijn (Chapter 13) propose that exposure to risk content via media influences children’s and adolescents’ cyberbullying perpetration. They have empirically tested this model in various studies (see den Hamer & Konijn, 2015; den Hamer, Konijn, & Keijer, 2014). The establishment of laws concerning cyberbullying also relates to the exosystem as well since the goal of such laws is to reduce cyberbullying and penalize the perpetrators. Out of the systems mentioned in this paragraph thus far, the macrosystem has a bit more empirical connections supporting its role in cyberbullying perpetration.

This research focuses on cross-cultural differences in cyberbullying involvement, typically between individualistic and collectivistic societies, with findings revealing greater levels of perpetration and victimization among individualistic countries. The chronosystem has been less examined, and there is no chapter in this book that taps into this system’s role in cyberbullying among children and adolescents, except Chapter 1, which proposes factors related to this system that might impact involvement in these behaviors. Anonymity is one variable that has emerged as having a connection with the chronosystem. It is connected with the chronosystem as new information and communication technologies make it increasingly possible to remain anonymous when perpetrating cyberbullying when compared to traditional face-to-face bullying.

This does not indicate that traditional face-to-face bullying acts do not ever include anonymity, but that there is a greater potential to remain anonymous in the online environment. In addition, the online disinhibition effect is also something that is characteristic of our digital age. This effect suggests that the online environment includes increased anonymity and lacks visual and auditory cues, making people more disinhibited and leading them to do and say things that they never would in the offline world (Suler, 2004). The gaps in the literature lead to a variety of future directions when applying the social-ecological framework to cyberbullying involvement.

Despite ample literature focusing on the individual-level predictors of cyberbullying involvement, many of these studies utilize concurrent research designs. Follow-up research with longitudinal designs is needed. To address the gaps in the literature, future research should also focus on the contextual predictors of cyberbullying involvement. Chapters 19 through 21 focus on the prevention and intervention of cyberbullying involvement among children, adolescents, and college students. Wingate and Minney (Chapter 20) specifically address the need for a social-ecological approach to apply to the development of prevention and intervention programs aimed at reducing cyberbullying. In order to develop programs with long-term implications, programs must involve parents, students, teachers, and the community. Theory-based and empirically tested prevention and intervention programs need to be developed or revised with the desire to reduce cyberbullying through involving all members of our society.

Chapter 24

PRESCHOOL TEACHERS' PERCEPTIONS ABOUT THE DEFINITION AND MANIFESTATIONS OF BULLYING IN EARLY CHILDHOOD SETTINGS

Eleni N. Nikolaou^{1,*} and Georgios M. Markogiannakis²

¹Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

²Independent Researcher, M.Ed., Rhodes, Greece

ABSTRACT

The aim of the present research is to explore preschool teachers' perceptions about what constitutes bullying and the types of bullying behavior that they observe in early childhood settings. The sample of this research was 164 preschool teachers from Greece. They were administered a questionnaire that was based on previous research. Results indicate that the participants in this study recognize all forms of bullying (physical, verbal, relational). The results indicate that the preschool teachers of the sample have observed all types of bullying, verbal, physical and social exclusion. Destruction of children's property and spreading rumors was less frequent bullying behavior according to their responses. The data can contribute to the international literature as they record the manifestations of bullying in Greek early childhood settings, the frequencies of the various forms of bullying, the places where bullying occurs and the number of children involved in these incidents. Moreover, the findings indicate that early prevention of bullying is essential as the teachers of the present research argue that children exhibit all forms of bullying in preschool age.

Keywords: preschool teachers, school bullying, manifestations

INTRODUCTION

School bullying is a prevalent social phenomenon, which posits a global concern for the international school community. It is a group phenomenon which is manifested in early

* Corresponding Author's Email: enikolaou@rhodes.aegean.gr.

childhood settings (Reunamo et al., 2015). Moreover, all forms of bullying are displayed in preschool contexts (Davis, 2015). It is a form of aggressive behavior which is repeated over time and has the intention of hurting the victim. It also includes an imbalance of power (Olweus, 1993). Bullying episodes include acts of physical and relational aggression (for example, social exclusion) as well as verbal harassment and damage of property (Merrel & Isava, 2008). Espelage (2004) highlights that bullying is an ecological phenomenon which emanates from the complex interplay between the children, their families and peer groups, school communities and culture.

Early prevention and intervention are crucial for children's emotional and social adjustment as well as for their mental health. The aim of the present research was to explore preschool teachers' perceptions regarding the manifestation of bullying in early childhood. According to Gillies-Rezo & Bosacki (2003) prevalence rates of bullying in preschool age should be based on teacher ratings rather than self-ratings. The consequences of bullying include poor school adjustment, academic performance, and delinquency in adulthood (Shetgiri, 2013).

Perren and Alsaker (2006) assert that bullies and victims are characterized by distinct social behavior patterns. Bullies display high levels of aggressive behavior, are less cooperative and sociable and have a leadership role. Victims have low sociability, submissive social behavior, withdrawal and they lack leadership skills. They cannot assert themselves and they are vulnerable to victimization.

ETIOLOGY OF SCHOOL BULLYING

The social ecological model (Espelage, 2014) posits that behavior is influenced by the complex interactions among the various environmental structures containing the child. The microsystem refers to the interaction of the child with the immediate settings (family, school, peer group). The mesosystem is associated with the interrelations among two or more microsystems for example, between family and school. The effect of the exosystem is indirect. Neighborhood safety is a factor of the exosystem that affects children's behavior. The macrosystem is associated with culture social norms, such as state legislation (Bronfenbrenner, 1979). Individual characteristics of children such as age, gender, race ethnicity, health status, psychological functioning, depression, disability status are risk factors for school bullying. Family characteristics, such as consistent parental monitoring, exposure to family conflict, history of abuse and inconsistent parenting are also considered risk factors. On the other hand, supportive family relations and positive parent-child interactions can deter school bullying.

PREVIOUS RESEARCH STUDIES

Tepetas et al. (2010) argue that teachers define bullying incidents mostly as physical violence and disobedience and rarely consider verbal and psychological forms of bullying. Bullying episodes mostly occur in the classroom.

Humphrey (2013) conducted interviews with preschool teachers. They reported incidents that they considered bullying. Their responses included the following themes: exclusion,

aggression, teasing and gossiping. The reasons they gave to children's social exclusion were related to children's inability to do something, and the children's appearance and clothing. According to their answers bullies exclude the victims from the play group in order to get the objects they want, to gain power or control of the group, or gain popularity. They attributed physical bullying to lack of social skills (such as conflict resolution skills). They also reported teasing and name calling based on looks and possessions. The reasons they gave included the appearance of the child and that they could not do something. To sum up, they reported that the causes of bullying are status gain, lack of social skills, media violence and attention seeking. According to Humphrey, preschool teachers reported more often relational bullying.

Repo's research (2015) found that early childhood professionals find it difficult to distinguish between bullying and quarreling between children. Their answers to the interviews conducted, indicated that they are aware of the repetitiveness and power imbalance, which are the key characteristics of bullying. They also take into account the subjective experience of bullying and victims' difficulty to withstand different actions towards them. The most common form of bullying was social exclusion. The psychological forms of bullying (such as threatening) were also more frequent than physical bullying. Perren's research study (2000) also indicated that social exclusion was the most common form in preschool settings.

Preschool teachers in Davis's research (2015) observed three types of bullying (verbal, physical and relational bullying) and bullying roles in early childhood settings. They had some knowledge of all forms of bullying and demonstrated empathy towards the victims of all forms of bullying. They were also willing to intervene in bullying incidents. Teachers were more likely to intervene to incidents of verbal bullying and less likely to relational bullying, although their responses indicated that they were willing to respond to all bullying scenarios and display empathy for the victims. Moreover, they stated that they had little professional training. The rate of verbal bullying incidents reported was higher.

Psalti (2017) suggested that verbal bullying was evaluated as the most serious form of bullying in preschool settings followed by physical bullying and social. Her research also indicated that early childhood teachers expressed more sympathy towards the victims of physical and verbal bullying than the victims of social bullying and were more likely to intervene in physical bullying incidents. She pointed out the need of sensitizing early childhood teachers about the seriousness of all forms of bullying. Vlachou, Andreou, Botsoglou and Didaskalou (2011) argued that aggressive behavior is displayed twice as frequently in the playground rather than in the classroom, and the occurrences at the playground are longer in duration. Several characteristics of the playground, such as the ration of playground supervisors to children, active supervision, and playground rules affect children's behavior. Planning and arranging the layout of each learning center in preschool classrooms contribute to children's positive social interactions.

Trigka-Mertigka (2015) argued that preschool teachers regard that family characteristics such as marital problems, insecure attachment between parents and children, negative school experiences, lack of services for children with emotional and behavioural difficulties within school context are among the risk factors for bullying episodes according to preschool teachers.

Vlachou et al. (2011) asserted that the percentages of bullies and victims vary depending on the source of collecting data. The prevalence of victimization is higher according to self-reports, whereas the role of bully is more frequent according to peer nominations. Teachers are considered a more reliable source of information during preschool age, although they find it difficult to distinguish bullying from other types of conflict.

METHOD

The participants of this research included 164 preschool teachers from Greece. 23.2% of the participants were aged between 22 and 30 years. Out of the 164 participants, 90.2% (148) were females and 9.8% (16) were males. 35.4% of the participants were aged between 31 to 40 years, 32.9% between 41 and 50 years and 8.5% of them were above fifty years. 44.5% of the respondents have had between 1 to 10 years of experience, 28.7% had 11 to 20 years and 14% more than 21 years.

The data collection tool was a questionnaire which was based on previous research (Psalti, Kassapi & Deligianni-Kouimtzi, 2012). The first section of the questionnaire included demographic data regarding the highest level of education, the teaching experience, the age and gender of the participants. The second section included ten vignettes describing children's aggressive behaviors and teachers were asked to assess whether the behavior described could be classified as bullying. Then they were asked to record the frequency of various types of bullying observed at their school, the place that bullying took place and the number of children involved in bullying episodes. The data presented in this research paper are part of a wider research Table 1 shows the demographic data of the current research study.

Table 1. Distribution of frequencies of the demographic factors of the sample

<i>Gender</i>	<i>Frequency N=164</i>	<i>Percent (%)</i>
<i>Male</i>	16	9,8
<i>Female</i>	148	90.2
<i>Age</i>

<i>Work experience</i>		
1-10	73	44.5
11-20	47	28.7
>21	23	14

RESULTS AND DISCUSSION

Various scenarios regarding bullying incidents were presented to the preschool teachers of our sample. Then they were asked whether the scenario that described the behavior is considered to be bullying. They had to give a "Yes" or "No" answer. The first scenario was the following: "Child A is approaching child B which is one year younger, he takes his toys and tells him that if he speaks, he will hit him. This happens every day". 147 teachers (89.6%) responded that this is a bullying behavior, whereas 17 (10.4%) responded that this is not bullying.

Table 2. Distribution of frequencies of teachers' responses to the bullying vignettes

Vignette	Responses for "Yes"		Responses for "No"	
	<i>N</i>	<i>Percent</i>	<i>N</i>	<i>Percent</i>
1. "Child A is approaching child B which is one year younger, takes his toys and tells him that if he tells, he will hit him. This happens every day".	147	89.6	17	10.4
2. "Child C and his friend, almost every day wait for child D at the school's entrance, they surround him and start pushing him around and throwing his bag and jacket".	145	88.4	20	11.6
3. "Child D takes from child Z the album with his stickers to see it and tears it".	95	58.5	69	41.5
4. "Child H takes from child J the sticker album to see it and it tears it by accident. Child H is very sad about it".	27	16.5	137	83.5
5. "Child L makes fun of child M for his new haircut. Child M gets sad".	96	58.5	67	40.9
6. "Child N makes fun of Child X for his new haircut and then both of them begin to push each other and laugh".	58	35.4	106	64.6
7. "Child O plays quietly at the yard of the kindergarten with his peers, when a group of children is approaching them. One of these children, Child P, says: Do not talk to O, he ingratiate himself with the teacher, do not play with him. His playmates leave and he stays alone".	125	76.2	37	22.6
8. "Child P is spreading rumors and saying bad things about Child S to the class. Most children in the class make fun of Child S and he stays alone most of the time".	143	87.2	21	12.8
9. "Child P is spreading rumors and saying bad things about Child S to the class. Most children in the class make fun of Child S and he stays alone most of the time".	143	87.2	21	12.8
10. "Some students do not let a classmate play with them, because he is a boy".	46	28	118	72
11. "Some students do not let a classmate play with them, because she is a girl".	47	28.7	117	71.3
Note: N=164 Total Sample				

The second scenario that was presented to the teachers was the following: "Child C and his friend almost every day wait for child D at the school's entrance, circle him and start pushing him around and throwing his bag and jacket". 145 teachers (88.4%) answered that this was a

bullying incident, whereas 20 (11.6%) answered that was is not. The third scenario describes that “Child D takes from child Z the album with his stickers to see it and tears it”. 95 (58.5%) responded that this is a bullying behavior, whereas 69% (41.5%) responded that it is not.

According to the fourth scenario, “Child H takes the sticker album from child J to see it and tears it by accident. Child H is very sad about it”. 27 teachers (16.5%) recognized this as bullying, whereas 137 (83.5%) did not. The fifth scenario described the following behaviour: “Child L makes fun of child M for his new haircut. Child M gets sad”. 96 teachers (58.5%) identified this is a bullying behavior, 67 (40.9%) did not, whereas 1 (0.6%) did not respond.

The sixth scenario described that “Child N makes fun of child X for his new haircut and then both begin to push each other and laugh”. 58 teachers (35.4%) confirmed this as bullying behavior, whereas 106 teachers (64.6%) did not.

According to the seventh scenario “Child O plays quietly in the kindergarten playground with his peers, when a group of children approaches them. One of them, child P, says: Do not talk to O, he sucks up to the teacher, do not play with him. His playmates leave and he stays alone”. Most teachers, 125 (76.2%) considered this a bullying incident, whereas 37 (22.6%) responded negatively.

The eighth scenario describes that “Child P is spreading rumors and saying bad things about child S to the classmates. Most children in class make fun of child S and he stays alone most of the time”. Most teachers (143, 87.2%) responded positively that that was bullying, whereas only 21 teachers (12.8%) responded negatively. The ninth scenario stated that “Some students do not let a classmate play with them, because he is a boy”. Most teachers 118 (72%) responded that this was not bullying episode, whereas 46 teachers (28%) responded that they considered it to be bullying. The tenth scenario stated that “Some students do not let a classmate play with them, because she is a girl”. 117 (71.3%) considered this a bullying behavior, whereas 47 (28.7%) replied that it was not.

The responses of the preschool teachers of the sample indicated that they were aware of all forms of bullying and that they took into account the repetitiveness of the bullying behaviors, the power imbalance as well as the intention of the perpetrator. The vast majority of the sample was capable of recognizing all forms of bullying. Verbal bullying was recognized by the higher percentage of the participants. In addition, physical bullying was identified by a large percentage of the respondents. Spreading rumors was also identified by a very high percentage of the participants as well as social exclusion.

Preschool Teachers' Responses about the Frequency of Bullying Behaviors

Preschool teachers were asked to report the frequency of several bullying behaviors. They were given the description of the bullying behavior and they responded how many times they noticed these behaviors. The first description of bullying was the following: *A child or some children said bad words, made fun of or baited another child or some other children* (first vignette). As Table 3 shows, 12.2% (20 teachers) of the sample replied that this incident had never occurred at their school. The higher percentage 34.1% (56) responded that it occurred 1-2 times and 23.8% (39) responded that it occurred two or three times. 9.1% of the participants (15), that it is happening once a week and 20.7% (34 teachers) answered several times.

A Child (or some children) deliberately did not play with another child (or some other children), excluded it from play or completely ignored it (second vignette). As Table 4 shows,

17.1% of the respondents (28 teachers) replied that they had never observed such an incident at their school. 32.9% (54 teachers) responded that they had observed this incident 1-2 times and 17.1% (28 teachers) responded once a week. 13.4% (22 teachers) answered several times.

Table 3. Distribution of frequencies of teachers' responses to the first vignette

<i>"Child A is approaching child B which is one year younger, he takes his toys and tells him that if he speaks, he will hit him. This happens every day".</i>		
	Frequency	Percent
<i>Never</i>	20	12.2
<i>1-2 times</i>	56	34.1
<i>2-3 times</i>	39	23.8
<i>Once a week</i>	15	9.1
<i>Several times</i>	34	20.7
<i>Total</i>	164	100.0

Table 4. Distribution of frequencies of teachers' to the second vignette

<i>"A Child (or some children) deliberately did not play with another child (or some other children), excluded it from play or completely ignored it".</i>		
	Frequency	Percent
<i>Never</i>	28	17.1
<i>1-2 times</i>	54	32.9
<i>2-3 times</i>	32	19.5
<i>Once a week</i>	28	17.1
<i>Several times</i>	22	13.4
<i>Total</i>	164	100.0

Table 5. Distribution of frequencies of teachers' to the third vignette

<i>"A Child (or some children) hit, kicked or pushed another child (or some other children)".</i>		
	Frequency	Percent
<i>Never</i>	21	12.8
<i>1-2 times</i>	53	32.3
<i>2-3 times</i>	28	17.1
<i>Once a week</i>	30	18.3
<i>Several times</i>	29	17.7
<i>Total</i>	161	98.2
<i>Missing</i>	-9	3
<i>Total</i>	164	100.0

A Child (or some children) hit, kicked or pushed another child or some other children (third vignette). Table 5 shows that 12.8% (21 teachers) replied that they had never observed such an incident. The higher percentage, 32.3% (53 teachers) responded one or two times, 17.1% (28 teachers) two or three times, 18.3% (30 teachers) responded once a week and 17.7% (29 teachers) several times.

A Child (or some children) lied or spread bad rumors about another child (or children) and tried to make others not to like this child or children (fourth vignette). As table 6 shows, 46.3% of the sample (76 teachers) replied that this incident had never occurred, 28% (46 teachers) responded one or two times, 5% (27 teachers) two or three times, while 5.5% (9 teachers) replied once a week, and 3.7% (6 teachers) several times.

Table 6. Distribution of frequencies of teachers' responses to fourth vignette

<i>"A Child (or some children) lied or spread bad rumors about another child (or children) and tried to make others not to like this child or children"</i>		
	Frequency	Percent
<i>Never</i>	76	46.3
<i>1-2 times</i>	46	28.0
<i>2-3 times</i>	27	16.5
<i>Once a week</i>	9	5.5
<i>Several times</i>	6	3.7
<i>Total</i>	164	100.0

A child or some children took the toy or other things of another child (or some other children" or destroyed things of another child or children (fifth vignette). Table 7 shows that 26.8% (44 teachers) replied that they had never observed such an incident at their school, 32.9% (54 teachers) responded one-two times, 27.4% (45 teachers) responded two- three times, 7.3% (12 teachers) responded once a week, while only 4.9% (8 teachers) replied several times.

Table 7. Distribution of frequencies of teachers' responses to fifth vignette

<i>"A child or some children took the toy or other things of another child (or some other children" or destroyed things (of another child or children)"</i>		
	Frequency	Percent
<i>Never</i>	44	26.8
<i>1-2 times</i>	54	32.9
<i>2-3 times</i>	45	27.4
<i>Once a week</i>	12	7.3
<i>Several times</i>	8	4.9
<i>Total</i>	163	99.4
<i>Missing</i>	-9	0.6
<i>Total</i>	164	100.0

A Child (or some other children) threatened another child (or some other children) or forced another child (or some other children) to do things they did not want do (sixth vignette). As table 8 shows, 56.7% (93 teachers) reported that it had never occurred at their school, 26.2% (43 teachers) that it occurred one or two times, 4.3% (7 teachers) responded two or three times, 11% (18 teachers) once a week, 1.2% (2 teachers) several times.

Table 8. Distribution of frequencies of teachers' responses to sixth vignette

<i>A Child (or some other children) threatened another child (or some other children) or forced another child (or some other children) to do things they did not want to do.</i>		
	Frequency	Percent
<i>Never</i>	93	56.7
<i>1-2 times</i>	43	26.2

<i>Total</i>	164	100.0

The higher percentage of preschool teachers 81.1% (133 teachers) report that these bullying episodes are taking place in the school yard, whereas 18.9% (31 teachers) disagree as table 9 shows. This is in line with previous research that asserts that most bullying incidents occur at playground (Tepetas et al., 2010; Vlachou et al., 2011). This finding may indicate that increased supervision could limit the phenomenon of bullying.

Table 9. Distribution of frequencies of teachers' responses about the bullying incidents at school yard

<i>Bullying incidents took place at the schoolyard during the break.</i>		
	Frequency	Percent
<i>False (not valid)</i>	31	18.9
<i>True (valid)</i>	133	81.1
<i>Total</i>	164	100.0

As table 10 shows, 86% (141 teachers) reported that these incidents did not occur in the restroom, whereas 14% (23 teachers) disagree. The majority 69.5% (114 teachers) asserts that these incidents did not occur when the teacher was in the classroom, whereas 30.5% (50 teachers disagree) as table 11 shows. These findings are in line with previous research which supports that bullying incidents are displayed in the playground (Vlachou et al., 2011; Tepetas et al., 2010). Moreover, these data highlight the value of supervision of all areas of the school environment, as a high rate of teachers argue that the bullying episodes did not occur when the teacher was in the classroom.

Table 10. Distribution of frequencies of teachers' responses regarding the bullying incidents that took place at the toilets of their school

<i>"The bullying incident took place in the restroom".</i>		
	Frequency	Percent
<i>False (not valid)</i>	141	86.0
<i>True (valid)</i>	23	14.0
<i>Total</i>	164	100.0

Table 11. Distribution of frequencies about the bullying incidents that took place while a teacher was present

<i>"The bullying incident occurred inside my classroom while a teacher was present".</i>		
	Frequency	Percent
False (not valid)	114	69.5
True (valid)	50	30.5
Total	164	100.0

As table 12 shows, the majority stated (42.7%, 70 teachers) that a group of 2-3 children participated in bullying episodes, 25.6% (42 teachers) stated that different groups of children participated each time 3.7% (6 teachers) stated that it was a group of 4-9 children and 25.6% (42 teachers) replied that only a child was the perpetrator.

Table 12. Distribution of frequencies about teachers (teachers') responses regarding the number of children involved in bullying

<i>How many children participated in bullying incidents?</i>		
	Frequency	Percent
Mainly 1 child	42	25.6
A group of 2-3 children	70	42.7
A group of 4-9 children	6	3.7
Not the same children or group of children every time	42	25.6
Total	160	97.6
Missing	-9	4
Total	164	100.0

The above results indicate that the preschool teachers of the sample have observed all types of bullying, verbal, physical and social exclusion. Destruction of children's property and spreading rumors was less frequent bullying behavior. These findings are in line with previous research (Davis, 2015), which suggested that preschool teachers observed all types of bullying in early childhood settings.

CONCLUSION

The present study indicated the presence of bullying in Greek early childhood settings. Preschool teachers reported that physical, verbal and social exclusion occurred at preschool contexts. They were also capable of distinguishing bullying from other forms of behaviors which include direct or indirect aggressiveness based on the criteria of repetitiveness, intention and the subjective feeling of the victim. Preschool teachers' capacity to detect bullying as early as possible is crucial, as bullying has short-term and long-term consequences for both bullies and victims and the whole kindergarten group (Perren & Alsaker, 2006). Children's right to be educated in caring, respectful and safe school environments is highlighted by the United Nations Convention (1989).

Teachers are key agents in anti-bullying efforts, therefore their awareness and knowledge of all forms of bullying and their effects is fundamental to the effectiveness of bullying prevention and intervention (Yoon & Bauman, 2014). The recognition of bullying behaviors, knowledge about the types, the prevalence, signs and consequences of bullying are considered the first step of successful intervention (Marshall, 2012). In addition, it is critical that the teachers incorporate the discussion of bullying into their daily instruction and record bullying incidents. Professional development opportunities could expand their knowledge and train them in effective prevention and intervention.

Moreover, it was found that preschool teachers regard teacher training, classroom activities for diversity tolerance, the development of empathy as well as the collaboration between school and family as essential measures for bullying prevention (Nikolaou & Markogiannakis, 2017). The occurrence of bullying at early years has significant implications for the design and the implementation of interventions, which should be tailored to the needs of each early childhood context. Moreover, school bullying is associated with the peer group context (Repo, 2015), thus the whole kindergarten group should be trained to detect the various types of bullying and intervene when bullying occurs. School-Family collaboration and the implementation of socio-emotional programs is of utmost importance for bullying prevention according to teachers (Stamatis & Nikolaou, 2016). Their contribution to preventive initiatives is vital. Bullying is a systemic phenomenon which requires the participation of all stakeholders of the school community to policy development, prevention and intervention.

Chapter 25

TEACHERS' ATTITUDES TOWARDS BULLYING

Christina F. Papaeliou*

Department of Preschool Education Sciences and Educational Design,
University of the Aegean, Rhodes Island, Greece

ABSTRACT

The present study examined teachers' attitudes towards three forms of bullying i.e., physical, verbal and relational. Eighty two teachers from different educational levels (preschool, primary school and high school) completed a vignette based inventory measuring seriousness of the bullying incident, causes, feelings of responsibility and self-efficacy and coping strategies. Although it seems that teachers consider physical bullying as the main form of bullying, they do not show any differences in their emotional reactions and feelings of responsibility and of self-efficacy towards the three forms of bullying. However, differences were observed in teachers' reactions towards the victim and the perpetrator. Discussion highlights the necessity for in-service training in order to raise awareness among teachers that both perpetrators and victims may need some form of intervention.

Keywords: physical bullying, verbal bullying, relational bullying, self – efficacy, victim, perpetrator

INTRODUCTION

Bullying is recognized as one of the major problems facing schools worldwide today. Bullying is not considered as synonymous to violence or aggression (Harachi et al., 1999), but is a particular form of both and is identified through the following traits: the intention of offending or harming the victim, the persistence of the abusive behaviors in time, the asymmetry of power (actual or perceived), and the social nature of the phenomenon, that is, the presence of witnesses who may intervene, siding with the victim or adding to the bully's

* Corresponding Author's Email: papailiou@rhodes.aegean.gr.

behavior (Olweus et al., 1999; Sharp & Smith, 1994). Three main forms of bullying can be distinguished, i.e., physical, verbal and relational. Physical and verbal bullying are characterized as overt forms, while relational bullying is characterized as covert form of social aggression (Power-Elliott & Harris, 2012). While physical bullying tends to decrease with age, relational bullying tends to persist (Crick et al., 2002).

Although bullying has been a problem in schools for generations, it has been studied systematically since the 70's (Ross, 1996). A large – scale cross national study of bullying and victimization among adolescents in 40 countries (Craig et al., 2009) revealed that exposure to bullying varied across countries, with estimates ranging from 8.6% to 45.2% among boys, and from 4.8% to 35.8% among girls. Adolescents in Baltic countries reported higher rates of bullying and victimization, whereas northern European countries reported the lowest prevalence. Boys reported higher rates of bullying in all countries, while rates of victimization were higher for girls in 29 of 40 countries. Rates of victimization decreased by age in 30 of 40 (boys) and 25 of 39 (girls) countries.

In Greece the most extended research was carried out in 2010 in a sample of 4.944 adolescents (6th grade primary school, 2nd grade junior high school and 1st grade high school) recruited from 306 school units. According to the findings, 8.5% of the adolescents reported that they had been bullied 2 to 3 times per month in the last two months, with boys and older students reporting more incidents. A percentage of 15.8% reported that they bully other students, with boys reporting this behavior three times more often (23.4%) compared to girls (8.8%). It was also shown that both victims and perpetrators come from dysfunctional families with high rates of psychopathology and parental unemployment.

It is consistently documented that bullying causes serious short – and long – term problems in personality as well as social and academic functioning of both victims and perpetrators. Specifically, it has been found that bullying is associated with internalizing problems, such as anxiety and depression and externalizing problems, such as disruptive disorders and attention deficits, peer rejection, early school dropout, involvement in crime, and adult psychopathology (Reid et al., 2004; Twemlow et al., 2001; Craig, 1998; Crick, 1995; Parker & Asher, 1987).

School bullying also affects seriously school climate and has become a major concern for teachers, since they face the challenge to deal with a perpetrator and a victim (Yoon & Kerber, 2003). Teachers clearly can play an important role in tackling school bullying by helping to develop and implement a school policy, working with children, liaising with parents of children involved, and cooperating with professionals. However, in order to achieve this goal teachers need to be well-informed about bullying and confident in dealing with it.

Poulou and Norwich (2002) proposed a model which interprets the factors that may affect teachers' decision to take action in order to deal with a problem in their class. This model suggests that teachers may use a variety of strategies such as referral to external agents (i.e., specialists, parents) and the use of positive and negative incentives or other teaching approaches. Nevertheless, the actual use of these strategies was shown to be influenced by teachers' emotional responses towards children, judgements of their self – efficacy as well as their perceptions of others' expectations in relation to children's problems. In Ajzen & Fishbein's (1969) terms these perceptions are called subjective norms. In turn, teachers' emotions, feeling of self – efficacy and subjective norms are supposed to be influenced by the causal attributions. Following this ecological perspective, this study attempts to explore factors not only deriving from the child herself, but also factors deriving from her immediate environment such as the family, and the wider environment formed by teachers and school.

Given that teachers are the individuals most likely to handle bullying incidents, their responses should be carefully examined. However, there are relatively few studies focusing on teachers' attitudes towards bullying in Greece. Amanaki and Galanaki (2014) examined definitions of school bullying and perceived seriousness of bullying in 522 preservice teachers. Results showed that a considerable percentage of prospective teachers regarded bullying as a serious problem. In their definitions of bullying, they placed emphasis on physical and verbal bullying, on the perpetrators' intention to produce harm and on the victim's suffering (empathy).

However, other important facets of bullying, such as duration, repetition, imbalance of power between bully and victim, the unjustified, unprovoked and group nature of bullying behavior, were much less frequently reported. Also, prospective teachers had a considerable difficulty to include in their definitions references to social exclusion as a specific form of bullying. Similar results are also reported by Pateraki & Houndoumadi (2001), Athanasiadou & Psalti (2012) and Markogiannakis, Nikolaou & Karagianni (2016).

Nevertheless, to our knowledge there is no published study in Greece examining teachers' feeling of responsibility and self – efficacy in coping with different forms of bullying, their reactions towards the victim and the perpetrator as well as the actions they take, in order to deal with the problem. The present study aims to contribute to the relevant literature by highlighting these issues.

METHOD

Participants

In the present study participated 82 teachers, 27 (33%) men (mean age 40.9 years) and 55 (67%) women (mean age 38.0 years). Forty participants (49%) were primary school teachers, 29 (35%) were preschool teachers and 13 (16%) were high school teachers. The vast majority, 67 (82%) teachers, were employed in the public sector, while 15 (18%) teachers were employed in the private sector. Teachers had on average 12.5 years of experience (range 2 – 31 years).

Measures

For the data collection three inventories were used consisting of a vignette. Vignettes are widely used in attitudinal research, because they may mitigate social desirability effects by placing the issue outside the respondent's personal experience (Wilks, 2004; Barter & Renold, 1999). Also, this method may eliminate potential observer effects, since observation of teachers by researchers is likely to influence their behavior (Gould, 1996). Poulou (2001) notes that vignettes are the most appropriate method for understanding teachers' cognitive and affective responses to specific incidents, which provide essential information for designing effective training programs.

The vignette in each questionnaire described a different form of bullying. Vignettes were adapted from the Bullying Attitude Questionnaire (Craig et al., 2000), using three scenarios

regarding each form of bullying i.e., physical, verbal and relational. The scenarios are described below.

Scenario 1 [Relational Bullying]

During project time you overhear one student saying to another: *“If you don’t let me have the purple marker, I won’t invite you to my birthday party.”* This is not the first time you have heard this student saying this type of thing.

Scenario 2 [Physical Bullying]

Your class is getting ready for the break time and the students are in line at the door. You hear one student saying to another: *“Hey, give me your lunch money or I’ll give you a fat lip.”* The student complies at once. This is not the first time this has happened.

Scenario 3 [Verbal Bullying]

During project time you overhear one student calling another student *“bespectacled.”* The later child tries to ignore it, but finally he/she frowns.

The inventories included a questions about the seriousness of the bullying incident and a question on the gender of the children involved in it as victims and perpetrators. The rest of the inventory was adapted from the inventory developed by Poulou and Norwich (2002) for the study of teachers’ perceptions and includes three parts. The first part refers to the possible causes of bullying and consists of 23 items, the second part refers to teachers’ reactions and consists of 16 items, while the third part refers to teachers’ actual coping strategies and consists of 18 items. Teachers were asked to note on a five point Likert scale how possible a specific statement to be true for them is, as regards both the victim and the perpetrator. Items measuring the same feature were grouped together and a mean was calculated. Means were classified in three categories indicating low, moderated and high possibility (<2.5 , $2.5 - 3.5$, >3.5 respectively). Also, there were questions about demographic characteristics of the sample. Twenty six teachers completed the vignette with scenario 1, 30 teachers completed the vignette with scenario 2 and 26 teachers completed the vignette with scenario 3.

Procedure

Researchers administered the instrument, together with an information letter and a consent form. Teachers completed the questionnaire at school, leaving them in dedicated boxes that had been left in different spots of the building, specially designed to guarantee privacy and anonymity. Response rate was 63%. On the box there was a label indicating the title of the study, the expected collection date and contact details of the researchers. The questionnaires were collected 8 working days later.

RESULTS

An ANOVA test with LSD post hoc comparisons was carried out, in order to explore teachers’ perceptions about the seriousness of each bullying form. According to the findings, both physical and verbal bullying were considered as very serious, while relational bullying

was considered as moderately serious. In addition, physical bullying was considered as the most serious form of bullying ($F = 32.6$, $p < 0.001$). Chi square test demonstrated that teachers related different forms of bullying with boys and girls. In particular, boys were more often considered to provoke physical and verbal bullying, while girls were more often considered to provoke relational bullying. Moreover, girls were shown to accept intimidation more often compared to boys ($\chi^2 = 61.1$, $p < 0.001$).

As regards causes of bullying for the perpetrator, results showed that it was highly possible for teachers to attribute physical bullying to the family and moderately possible to attribute it to the child, the teaching staff or the school. On the other hand, both verbal and relational bullying were moderately possible to be attributed to the family, the child, the teaching staff or the school (Table 1).

Table 1. Possible causes of bullying for perpetrators

Possible causal factors	Forms of bullying		
	Physical	Verbal	Relational
Family	3.6	3.3	2.7
Child	2.9	2.8	2.7
Teacher	2.7	3.1	2.5
School	3.3	3.1	2.8

In relation to the causes of bullying for the victim, results show that it is moderately possible for teachers to attribute physical bullying to factors related to the school and the teaching staff, while it is least possible to attribute physical bullying to the family or the child. Similarly, verbal bullying was moderately possible to be attributed to the school and the teaching staff, but least possible to be attributed to the family and the child. Relational bullying was moderately possible to be attributed to the school and least possible to be attributed to the family, the child or the teaching staff (Table 2).

Table 2. Possible causes of bullying for victims

Possible causal factors	Forms of bullying		
	Physical	Verbal	Relational
Family	2.4	2.3	2.1
Child	1.9	2.0	1.9
Teacher	2.5	2.9	1.7
School	3.0	2.9	2.6

As regards emotions, it was highly possible for teachers to express negative emotions for the perpetrators and moderately possible to express negative emotions for the victims in all three conditions. This difference was statistically significant ($t = 6.88$, $p < 0.001$). Negative emotions for perpetrators was significantly positively correlated with causal attribution to the child ($r = 0.443$, $p < 0.001$). On the other hand, it was highly possible to express sympathy for perpetrators, but moderately possible to express sympathy for the victims ($t = 4.9$, $p < 0.001$). Teaching experience was significantly positively correlated with expression of sympathy for perpetrators ($r = 0.349$, $p = 0.003$).

Moreover, it was moderately possible for teachers to feel responsible and self-efficient to deal with the problem for both perpetrators and victims ($t = 0.2$, $p = 0.820$ and $t = 1.6$, $p = 0.114$ respectively). It is also worth noting that these feelings did not differ according to the form of bullying. However, it was moderately possible to undertake action in order to cope with perpetrators, but it was least possible to undertake action for victims and this difference was statistically significant ($t = 4.6$, $p < 0.001$). In addition, it was highly possible for teachers to ask external agents for cooperation in order to deal with perpetrators, but it was moderately possible to ask other individuals and sectors for cooperation for victims. This difference was also statistically significant ($t = 4.6$, $p < 0.001$). Teachers' intention to ask external agents for cooperation did not differ according to the form of bullying for perpetrators. However, it was more highly possible to ask external agents for cooperation in order to deal with the victims in incidences of physical bullying than in incidences of relational bullying ($F = 3.6$, $p = 0.034$).

Pearson r correlation coefficient tests showed that teachers' action in order to deal with perpetrators was significantly positively correlated with their feelings of responsibility ($r = 0.428$, $p < 0.001$) and self-efficacy ($r = 0.404$, $p < 0.001$) as well as with their negative emotions for the child ($r = 0.300$, $p = 0.009$). Also for these children teachers' willingness to ask external agents for cooperation was significantly positively correlated with their perception about the severity of the incident ($r = 0.269$, $p < 0.001$), their feelings of responsibility ($r = 0.347$, $p = 0.002$) and self-efficacy ($r = 0.420$, $p < 0.001$) as well as the sympathy for the child ($r = 0.360$, $p = 0.001$). For victims teachers' coping strategies were also significantly positively correlated with their feelings of responsibility ($r = 0.477$, $p < 0.001$) and self-efficacy ($r = 0.491$, $p < 0.001$) as well as their feelings of sympathy for the child ($r = 0.513$, $p < 0.001$). Also, for these children willingness for cooperating with external agents was significantly positively correlated with their perception about the severity of the incident ($r = 0.270$, $p = 0.016$), their feelings of responsibility ($r = 0.431$, $p < 0.001$) and self-efficacy ($r = 0.370$, $p = 0.001$) as well as the sympathy for the child ($r = 0.344$, $p = 0.002$).

DISCUSSION

The aim of the present study was to investigate teachers' perceptions about different forms of bullying as well as their emotions and reactions towards both the perpetrators and the victims. For the investigation of these issues an inventory presenting vignettes was distributed in preschool teachers, primary school teachers and secondary school teachers.

According to the findings, teachers at all levels of education in this sample perceived physical bullying as more serious than verbal and relational bullying, while they perceived relational bullying as the least serious form of bullying. This finding is in agreement with findings from studies carried out in other Western countries (Craig et al., 2011; Boucan & DelRio, 2006) and in Greece (Stamatis & Nikolaou, 2016) and reveal that although students are equally distressed by all forms of bullying, schools tend to respond to physical and some verbal bullying and to ignore indirect or relational bullying. However, as Nishina and colleagues suggest (Nishina & Juvonen, 2005; Nishina, 2004) these results are alarming, since relational bullying has also harmful long – lasting effects on perpetrators and victims.

Moreover, in accordance with findings from other studies (Wang et al., 2009; Owens et al., 2000; Bjorkvist, 1994), it was demonstrated that boys and girls express aggression in different

ways; boys engage more in physical or verbal bullying, whereas girls use spreading rumors and social exclusion as bullying tactics. Gender differences in direct and indirect forms of bullying may be related to differences in socialization between the two genders.

As regards causal factors of bullying, results of the present study revealed that teachers attribute different causal factors for the same forms of bullying in perpetrators and victims. In particular, teachers reported that perpetrators may exercise physical, verbal or relational bullying mainly due to family factors such as low socio – economic status or parental style, and secondarily due to traits of personality or some form of developmental disorder. On the other hand, teachers of this sample believe that some children become victims of physical, verbal or relational bullying due to factors related to school, such as lack of services for children with problems, curriculum that does not respond to children's interests, large number of students in a class and poor school organization, or due to factors related to the teaching staff, such as teaching method or teachers' personality and behavior. In a similar vein, Ahmed and Braithwaite (2004) reported that perpetrators could not be classified on the basis of school variables, while victims could not be classified on the basis of family variables. Although this finding has not thus far been explained adequately, it is possible that children's aggressive behavior is attributed to family or child dysfunctioning. On the other hand, teachers believe that victimization is the outcome of school climate and organization and is not related to family dysfunctioning, child's personality or any form of developmental psychopathology.

However, relevant studies reveal that victims report high levels of anxiety and depression. Also, it is worth noting that in some cases victims turn to perpetrators and reversely and the bully-victims often manifest disruptive disorders or depression (Kumpulainen et al., 2001). If this proves to be the case, both victimization and bullying behaviors may be a sign of underlying psychopathology that may assist in the identification of children in need of psychological interventions.

In addition, teachers avoid to express negative emotions for both perpetrators and victims. However, negative feelings for perpetrators are more intense in cases teachers attribute the cause of the behavior to characteristics of the child, such as personality, level of intelligence or developmental disorders (e.g., Attention Deficit Hyperactivity Disorder or Autism Spectrum Disorder). An interesting finding was that teachers expressed more sympathy for perpetrators than for victims, in all conditions of bullying, namely physical, verbal and relational. Therefore, it seems that when teachers deal with perpetrators, they experience more intense emotional reactions, either positive or negative, than when they deal with victims. This apparently contradictory findings may be explained if one takes into account teachers' causal attribution. Indeed, teachers may dislike students who hinder the lesson, but at the same time they may sympathize them, because they feel they need some form of intervention. In contrast to the present finding that teachers experience similar positive feelings for victims in all conditions of bullying, Yoon and Kerber (2003) report that empathy for victims was significantly less for relational bullying than for physical or verbal bullying.

Moreover, the present study showed that teachers feel equally responsible and self – efficient to deal with both perpetrators and victims in all forms of bullying. However, they showed greater intention to undertake action themselves or ask external agents for cooperation in order to deal with the perpetrators. Other studies (Byers et al., 2011) reveal that teachers with higher levels of self– efficacy were more likely to intervene in overt bullying incidents i.e., verbal and physical, but not covert incidents i.e., relational. Additionally, a greater percentage of the teachers handled bullying incidents by focusing on the bully and ensuring that the bully

was suitably punished. Teachers' perceived self-efficacy in handling bullying is an important factor to be taken into consideration with responding to and handling bullying. Research revealed that some teachers did not feel confident in their ability to resolve bullying incidents and that this had an effect on their willingness and ability to involve themselves in dealing with bullying (Mishna et al., 2005; Boulton, 1997).

Conclusively, in accordance with other studies, the present study demonstrated that although teachers consider physical bullying as the main form of bullying, they do not show any differences in their emotional reactions as well as feelings of responsibility and self – efficacy in dealing with each incident. However, differences were observed in teachers' reactions towards the victim and the perpetrator. In particular, teachers experience more intense feelings, positive and negative, for the perpetrator than they victim and they are more willing to take actions or ask external agents for help, in order to copy with them. These results reveal the necessity for in-service training aiming to raise awareness among teachers that both victims and perpetrators need some form of intervention, since both may suffer from some form of psychopathology.

ACKNOWLEDGMENTS

This study was carried out in collaboration with 4th year students (2017 – 2018) of the TEPAES, University of the Aegean, Greece.

Chapter 26

BULLYING VIA VIOLENT COMMUNICATION BY EARLY CHILDHOOD EDUCATION TEACHERS DURING TEACHING PROCESSES: TWO OBSERVATIONAL STUDIES

Panagiotis J. Stamatis*

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

The teaching process is actually a multi-communication process like a puzzle picture consisting of numerous communication interactions among participants. The teaching process may be interesting or not, pleasant or unpleasant, friendly or hostile etc. depending mainly on the teacher's attitude, his/her verbal expressions and nonverbal behavior in the classroom. Especially the words teachers utilize while teaching students of early childhood, the tone of their voice and body language may create positive or negative classroom conditions which affect the relationships developed among the teacher and the attending children.

This chapter, based on two observational studies of teachers' communication behavior during teaching processes, focuses on the way they prefer to communicate in the classroom. It also examines teachers' verbal expressions in classroom as well as their body language, a basic nonverbal communication aspect, affecting the relationships among classroom participants especially in early childhood school units. Moreover, emphasis is put on teachers' verbal expressions and nonverbal behavior that may help lead children in addressing bullying and oral violence as teachers are usually considered role models especially for early childhood pupils.

INTRODUCTION

Are you a teacher of early childhood children or do you have any teaching experience regarding that age group? If the answer is yes, you may know that you have to deal with many difficulties on a daily basis apart from the many enjoyable and cute moments especially when the children are being collaborative following the common rules of teaching like active listening, participating, silent attending etc.

Also, you may know that using negative remarks to correct a child's misbehavior such as speaking and laughing loudly, during the lesson is considered to be unproductive. In such cases, teachers may remark and reprimand the child as well as sternly looking at them. Moreover, a teacher could normally discourage inappropriate behavior that disrupts the teaching by using different facial expressions. When the child does not stop the behavior that is disrupting the class, teachers usually become upset and express negative feelings towards him/her, hurting their relationship and reducing the initial confidence, the child may have established with his/her teacher.

Situations like that previously mentioned, present a very simple example which shows a kind of violent communication expressed by the teacher in an early childhood classroom, even though teacher as s/he is a beloved person for the children should never develop such a behavior; even more during classroom teaching processes. On the other hand, communication in relationships between teachers and students, as shown by a large number of related studies, must be characterized at least by calmness, courtesy and mutual respect. Violent communication has no place and role in teaching processes. Teachers should never show such hurtful behavior which is considered to be a hidden violence equal to verbal and nonverbal bullying (Stamatis, 2011; Kodakos and Stamatis, 2002; Edwards and Edwards 2001; Richmond and McCroskey, 1997).

The relevant bibliography stresses that both the process and the content of communication developed between a child of early childhood and a teacher in the classroom, as well as other factors such as interpersonal relationships, communicative style, tone of voice, posture and body language in general, along with the vocal shades and sound fluctuations of the teacher or the pupil, may create the special communication feature of every pedagogical interaction (Vrettos, 2014; Kodakos & Polemikos, 2000; McCroskey, 1996). This feature may positively or negatively contribute to the classroom climate development. It may even exude or be inspired by positive or negative emotions that improve or hinder the effectiveness of classroom communication. In general, it is well known that effective communication during the teaching process generates considerable results in learning, relationship building and academic performance of children (Hadzigeorgiou, 2014; Stamatis, 2013).

On the contrary, the lack of effective communication usually causes tension, irritation and conflict among classroom interactants which may lead to school bullying or even to four types of child abuse, namely, *physical*, *emotional*, *sexual*, and *neglect* (Tell et al., 2006). Physical abuse is the threat of or act of physical violence against the child by another person. Emotional abuse involves coercive verbal and nonverbal behavior such as insults or slamming doors, not directed at the child's physical body but at their emotions and feelings of self-worth. Sexual abuse is forced or coerced sexual behavior imposed on the child by an older person. Neglect is the denial of basic human care that is required by the child in order to live a healthy life. Neglect can be either emotional or physical.

Any type of violence or abuse may be defined as the ability to impose one's will on another person through the use of verbal or nonverbal acts, or both, in a way that violates socially acceptable standards inflicting physical or psychological pain, injury, or suffering. The range of abusive behavioral patterns includes mild forms of verbal intimidation, severe beatings, and extremely violent rapes and homicides. Violence ranges from carefully planned attacks to sudden emotional outbursts inflicting injury on other persons. Abuse is usually marked by a power differential with the abuser in a superior position of power over the abused (Cahn & Lloyd, 1996).

Within this framework, violent communication or communication which includes violence could be defined as a form of communication which restricts liberty, denies recognition of needs, diminishes a person's worth and/or blocks compassion. This kind of communication is often the result of manipulative or coercive language that induces fear, guilt, shame, praise, blame, duty, obligation, punishment, and/or reward. Bearing in mind that communication is a social skill which aims at good human relationship establishment, violent communication or communication enclosing apparent or hidden violence through verbal or nonverbal processes is not a genuine form of communication after all. Actually, it could be characterized as "para-communication" which, in this case, involves evil intentions and purpose or hypocritical communication and miscommunication, as well. Referring to the relationship between violence and communication, Blumenthal (2006) aptly argues that "violence is a communication at such a primitive level that it bypasses thought altogether, and consequently the dialogue between the victim, the perpetrator and society occurs largely at a level that is beyond awareness." p. 4.

Violent communication usually occurs, when someone utters offending words or phrases aiming at hurting someone else. Violent communication may be present even while thinking, through self-talk or imagined conversations; and during the process of listening, when someone abuses the ears of another person due to loud voice. As correctly mentioned in a paper recently published by Heartland Community College, common ways that violent communication occurs are through:

- a) *Moralistic judgments and evaluations of others* which include insulting, putting people down, labeling, criticizing, diagnosing, or viewing someone as "wrong."
- b) *Denial of responsibility for our own feelings, thoughts, and actions* which includes blaming our feelings, thoughts, and actions related to others, vague and impersonal forces, authority, policies, rules, regulations, social or gender roles, or uncontrollable impulses instead of our own choices and needs.
- c) *Demands* which include an implied or explicit threat of blame, punishment, or reward, and
- d) *Blocking compassion* when someone's behavior revolves around intellectual understanding leading to an effort to "fix" a situation by providing feedback which advises about one's ups and downs, sympathizes with, educates, consoles, tells a story, corrects, explains, or interrogates a person.

Basic human needs are similar to those presented in Maslow's Hierarchy of Needs, namely, physical well-being, connection, honesty, entertainment, peace, autonomy, meaning, etc. (Maslow, 2011). There are basic human needs that we all share as opposed to specific actions we would like others to take. Violent communication does not belong to the basic human needs.

On the contrary, what humans need is nonviolent communication which suggests that people must contribute to their own and others' well-being at any time with no hesitation or personal profit. The development of nonviolent communication, especially in early childhood classroom environments, increases the likelihood of mutual giving and receiving because it assists children and teachers on recognizing and fostering the joy one feels when he/she meets the basic human need of contributing to their own and others' well-being. In that way, people who accept nonviolent communication as a better way of living, keep themselves far away from any kind of abuse or bullying, so as we can use a modern and alternative term for describing aggressiveness in school and society.

In case that a worldwide acceptable definition about nonviolent communication should be reached, one can take into consideration what Rosenberg (2015) has stressed about this topic: "Nonviolent communication is a 'compassionate' communication process, is communication that maximizes liberty, enhances understanding of the relationship between feelings and needs, promotes equality, and creates compassion. It involves understanding that our feelings are a result of our basic human needs being met or unmet. When our needs are met, we feel 'positive' emotions, such as joy, delight, confidence, inspiration, etc. When our needs are unmet, we feel 'negative' emotions, such as annoyance, tension, fatigue, yearning, etc."

Teachers of early childhood students know that not only nonviolent communication but also social skills development in the classroom like emotional intelligence, collaborative learning strategies etc., can be regarded as the corrective aspect of discipline, thus, preventing inappropriate behavior of learners (Van der Merwe, 2016; Stamatis, 2015). If someone speaks in a violent way to others, they may do what the former demands because of fear, guilt, shame, praise, blame, duty, obligation, punishment, or reward. Although someone could control others' behavior in this way, it is always preferable to communicate nonviolently with them. Furthermore, it is proper to communicate every time with calmness, compassion and politeness avoiding bullying patterns provided unwillingly or/and subconsciously (Stamatis & Nikolaou, 2016). That might easily happen, in cases of teachers in early childhood education dealing daily with children at a sensitive age on the personality development process.

It is well known that in-school violence and bullying are being studied in various forms in contemporary academic reality worldwide. One such form is related to the communication behavior that teachers develop through verbal or nonverbal communication during teaching. Another one relates to the communication behavior children express to teachers, classmates or their parents. By investigating or studying violent communicative behavior and bullying situations that occur in schools, educators and psychologists reveal various factors related to those behavior, which are mainly dependent on the psychological and emotional state of individuals who develop such manners. Also, experts examine the levels of stress that may be experienced by students and teachers due to the increasing demands of the educational system, the parental expectations for their children's academic and social excellence, or the desired achievements for teachers or the school unit where educational fees are required.

Violent communication gives birth to bullying. Instead, effective and nonviolent communication interactively and positively affects interpersonal relationships of each school's community members and consequently the school climate, academic performance, and many other parameters and activities of the educational process. Therefore, the issue of violence manifested in in-school communicative behaviors at all educational levels (preschool, primary, secondary and tertiary education), becomes particularly interesting among all researchers in the scientific fields of psychology, sociology, pedagogy and communication education. It becomes

even more intriguing for scholars, when it is linked to bullying and violent communication developed by verbal expressions and nonverbal behavior of early childhood teachers during the process of teaching.

Considering what has already been mentioned within the framework of the above theoretical issues, two observational studies provide evidence about violent communication and bullying presented through verbal expressions and nonverbal behavior of early childhood teachers during teaching processes. Study 1 aims to shed light on some types of communication behavior which are developed by preschool and early primary school teachers examining whether violent communication and bullying take place, consciously or not, during teaching processes. The summary of this study which was initially published in 2017 in the *International Journal of Criminology and Sociology*, volume 6, pages 166-171 is presented below. Study 2 inspects some forms of nonverbal communication behavior developed by preschool teachers in regard to communication violence and bullying during the teaching process of a painting activity.

STUDY 1

Purpose

This study, based on observations of teachers' communication behavior during teaching processes, focuses on the way they choose to communicate with children as well as their verbal expressions regarding the classroom climate conditions (Stamatis, 2017). In addition, the study examines the teachers' nonverbal behavior, which affects the relationships among classroom participants in the school environment. Emphasis is put on verbal expressions and nonverbal behavior of teachers that may lead to violent communication and bullying since teachers (and parents), more than anyone else, can be behavioral patterns/models, especially for children of early childhood.

Method

This study was conducted by P. J. Stamatis in May 2017. The whole project was based on the principles of research ethics and on techniques of an observational study as the present study could be classified. The *sample* of this study consisted of six (6) preschool teachers working in six kindergarten classrooms, where one hundred and fourteen (114) preschoolers (aged 4-6, 52 boys, 62 girls) attended the lessons and four (4) elementary school teachers working in primary school classrooms, where ninety (90) pupils (aged 7-8, 47 boys, 43 girls) attended the lessons. All teachers were women. All kindergartens and elementary schools of this study were situated in the City of Rhodes Island in Greece. The *data collection* instrument of the study was based on observations of the preschool and elementary school teachers concerning their communication behavior during the teaching process. Basic elements of teachers' communicational behavior were included on a specific data sheet where the researcher marked the appropriate communication behavior which could appear in any face-to-face interaction among a teacher and a child.

The researcher had to tick the appropriate box, recording the communication behavior of the teacher related to violence such as: (a) using words that offend children or sound sarcastic or ironic (verbal violent signs), (b) pinches, hits, pushes, pulls or angry facial expressions and mood (nonverbal violent signs); and (c) speaking loudly or nervously, screaming etc. (para-verbal violence signs). The teachers' behavior observation was decided to be the main methodology for the present research data collection. The whole concept was based on a cross-sectional study technique which took place in ten classrooms focusing on the communication behavior of every teacher-participant during ten teaching processes each lasting thirty (30) minutes. Teachers were informed about the theme of the present study and the terms of its conduction. The anonymity of the teachers was assured. The final conclusions were mainly based on the analysis and interpretation of the gathered quantitative and qualitative data produced by observations, as the following results show.

Results and Discussion

As the quantitative data analysis shows, only a few of each violence signs category (verbal, nonverbal, para-verbal) has been disclosed in every classroom. Most of these violent communication signs are related to nonverbal communication, followed by para-verbal and finally verbal communication. Bearing in mind that during a time period of thirty (30) minutes at least sixty (60) interpersonal interactions may be developed, someone could assume that the number of violent communication signs observed in teachers' communication behavior is not very high. Of course, if this number is compared to pedagogical concerns demanding zero violent communicative behavior in the classroom, it can be claimed that it becomes extremely and unexpectedly high. These kind of issues cannot be approached only by a quantitative point of view but also a qualitative one, which –even though it has been carried out- is not presented at the results of this chapter. Many of the results presented later in this chapter include statements' configuration based on the interpretation of all research data combined with communicative behavior displayed in the classrooms. The research on communication behavior issues faces many difficulties, as is well documented. One of them is the interpretation of body signs and messages.

According to the related bibliography about the ways of nonviolent communication behavior development through interpersonal interactions, every communicator should consciously choose the right words, body language and vocal signs to send out messages to the other person so as to effectively communicate with each other (Miller, 2015; Cahn & Abigail, 2014; Evans 2010). Especially in a school environment where teachers and children of all ages develop thousands of interpersonal interactions during the day, everybody –mostly the teachers- should be extremely careful about the way they express themselves. Knowing that even a word, a glance or an inappropriate voice tone may cause an immense trauma to the soul of a child, every single teacher should hinder his/her violent communicative behaviors and consequently the development of violent communication in every way (Stamatis, 2013). If a teacher working with early childhood students avoids to restrain his/her behavior in such a way they may traumatize the children, destroying trustfulness and any positive feeling they had already developed (Stamatis, 2015).

An interesting finding during the classroom observation has been the types of reactions developed by the teachers when realizing the inappropriateness of their verbal, nonverbal and/or para-verbal behavior. Teachers seemed to try hard to erase that bad moment from the children's minds –especially the one involved in a bad interaction- by making positive comments, jokes, funny grimaces, facial expressions and vocal changes to sound friendlier and even hilarious. They obviously regretted the violent communication moment they had permitted to develop. Both quantitative and qualitative results of this research may lead to the following conclusions taking into consideration the limitations and strengths mentioned below.

Conclusion

The analysis and interpretation of this research's results shows that all teachers convey violent communication behavior signs during their interpersonal interactions with children and classroom activities even at low levels. Such behavior is usually displayed to children who are not really collaborating with the teacher or their classmates, or those children who do not follow teacher's instructions at once. Hence, according to the study's findings and analysis, all teachers consciously or spontaneously show some kind of violent communication which is conveyed by violent communication signs created verbally, nonverbally or/and para-verbally. Most of them are nonverbal signs related to eye contact, facial expressions and grimaces. Verbal violent signs were less when comparing to the signs of the other two categories. This is possibly due to the fact that teachers usually better understand the use of speech than that of body language. Even more significant is the expression of para-verbal violent communication signs related to vocal characteristics. Those characteristics are quite evident in Arabian, Latin and Mediterranean cultures including the Greek one.

The experienced teachers seemed to regret disclosing their violent communication signs knowing that in this way they harm the interpersonal relationship in the classroom, and in general the climate quality. Thus, as it was observed, once they understood their mistaken behavior they tried to change it by showing a friendlier and pedagogically acceptable one. During short discussions carried out after every observational procedure between the researcher and the participant teacher, it was made quite clear that teachers absolutely dislike using inappropriate words or making ugly grimaces and screaming to rebuke children, especially to those in early childhood. Sometimes, teachers develop such behavior because of some children's inappropriate behavior. They do not feel ready enough to manage difficult situations within the classroom when some children are not collaborative. Thus, they lose the control of their communication behavior temporarily.

Despite what teachers believe about violent communication in everyday classroom activities, research in this field is extremely interesting and useful. Since teachers are communication patterns/models for children, if they underestimate the communication behavior they display every day, they may harm some children for the rest of their lives by teaching them the wrong way to communicate. It is clear that the wrong way of communication is the one which gradually provokes violence and bullying which is exactly what educators, parents and society are trying to prevent all over the world.

STUDY 2

Purpose

The second study examines nonverbal communication behaviors developed by preschool teachers in regard to violent communication and bullying during the teaching process of a painting activity, thus the main purpose was similar to that of the first one. Specifically, the researcher tried to investigate whether or not preschool teachers develop nonverbal violent communication within the classroom while participating in the most beloved activity of young children, that of painting.

Method

This survey was conducted in eight (8) public kindergartens in the city of Rhodes, Greece, where eight (8) preschool female teachers participated. The average number of preschool children per classroom was eighteen (18). The *sample* of the study consisted of preschool teachers and children. The researcher, after consulting with the principals of kindergartens and obtaining permission from the local education authorities, attended eight (8) painting teaching activities (sessions) –one per classroom– focusing on the observation of the nonverbal communication behavior of preschool teachers at three different levels. At the first level, the observation examined the processes of organizing the activity, namely preparing and providing instructions for its implementation, focusing on the use of voice (vocalics). At the second level, the observation was focused on postures and movements of the body (proxemics and kinesics). At the third level, the observation was centered on the assessment of children's paintings, specifically on facial expressions of preschool teachers as well as the expression of their emotions. The duration of each activity was forty (40) minutes. The investigator kept notes about the levels of observations and the most prominent evidence of nonverbal behavior as expressed during each teaching activities. Observations were recorded in a special observation key-sheet (*data collection instrument*), which was constructed by the researcher, and included only quantitative reports about the expression of nonverbal behaviors at each stage of the teaching process. At the next stage of the research procedure (*data collection procedure*), after the teaching process termination, the researcher noted down the occurrence of any nonverbal behavior of the preschool teachers regarding the use of their voice, the movements and postures of their body and their facial expressions. In this way, research data were gathered and analysed. The findings and conclusions are presented below.

Results and Discussion

Several related studies conclude that preschool teachers express themselves nonverbally in a better way than teachers at higher levels of education (White, 2016; Stamatis, 2014). Therefore, what the researcher of this study anticipates to find out is whether this view is also verified by his own observation of the nonverbal expressions of preschool teachers regarding the three main stages of teaching activities as stated above. Thus, the researcher focused on the

way the preschool teachers use their voice, postures and movements of their bodies along with the expressions of their faces. As shown in Table 1, which depicts the quantitative data gathered concerning nonverbal cues expression and their time duration and intention. The preschool teachers in all three phases of the teaching process express themselves nonverbally, with great ease and comfort. As far as the use of voice is concerned, it has been observed that, as they appeal to early childhood kids, they speak slowly and calmly, coloring their tone of voice when needed, in order to make what they say more comprehensible and sufficiently understood.

Table 1. Descriptive data of preschool teachers' nonverbal cues shown during the teaching process of painting activities – Estimation of time duration in minutes

Nonverbal cues per 30 min. teaching	PT* 1		PT 2		PT 3		PT 4		PT 5		PT 6		PT 7		PT 8	
Interpretation of cues	P	N	P	N	P	N	P	N	P	N	P	N	P	N	P	N
Voice & vocalics	18	1	15	3	24	5	21	2	24	3	18	2	20	1	19	1
Posture & kinesics	25	2	23	1	28	3	24	2	22	1	22	2	17	2	25	3
Facial expressions	18	4	24	2	19	1	20	3	19	2	25	1	23	1	17	1

PT: Preschool Teacher

P: Positive feelings according to interpretation of cues.

N: Negative feelings according to interpretation of cues.

In regards to the attitude and movements of the body, it was clear that preschool teachers were constantly mingling with the children, approaching, guiding and encouraging them to continue their painting while responding to their questions. Considering the facial expressions during the phase of paintings assessment, preschool teachers were using positive comments showing pleasant and supportive feelings, diligently avoiding any negative criticism. Their faces communicated great joy, admiration and satisfaction for the quality of every child's painting. These comments apply to almost all preschool teachers, although few exceptions were discovered.

Conclusion

As the results indicate, all preschool teachers effectively express themselves through a variety of nonverbal expressions during their teaching, trying to communicate with preschoolers in a comprehensive way. Thus, they utilize their voice in an attractive way to the children, speaking calmly and with clarity, changing the tone and pitch of their voice whenever necessary. At the same time, they move their bodies constantly walking among children, approaching them, touching and sitting next to them when children ask for their help. Moreover, they constantly express their feelings with facial expressions. It seems that the voice, the posture, the movements and the facial expressions of preschool teachers constantly emphasized their positive intentions and interest towards preschoolers, creating the conditions for a teaching process without communicative violence. All preschool teachers repetitively showed willingness for excellent communication development among mutual interactions, thus

providing a good example of communication to the children, teaching them how to cooperate by communicating calmly without any type of violence. Developing collaborative relationships in the classroom under these communicative conditions is a fundamental lesson for the children against school bullying.

LIMITATIONS AND FUTURE RESEARCH

As it is known, an observational study produces inferences from a sample where the independent variable is not under the control of the researcher because of ethical concerns or statistical constraints. Furthermore, a cross-sectional study, which is related to an observational study, involves data collection from a population, or a representative subset, at one specific point in time. Bearing in mind both of these issues, everyone could effectively imagine the limitations and strengths of the above presented studies. As it has been noticed, although observational studies cannot be used as reliable sources to make statements about the "safety, efficacy, or effectiveness" of a practice, they can still be useful for several reasons such as providing information about the "real world" practice and formulating research questions to be tested in subsequent experiments etc. Thus, the enrichment of both the above studies with an observation of variables such as training of teachers on teaching processes, on instructional communication and nonviolent expressive practices (verbal and nonverbal) could provide a significant contribution to enriching the findings of educators' communication behavior in the classroom during teaching.

ACKNOWLEDGMENTS

Cordial thanks to the preschool and primary school education teachers who participated in this study. Indeed, all of them participated voluntarily with great willingness. Their participation contributed to the realization of both studies' purposes in the best possible way.

Chapter 27

NONVERBAL EXPRESSIONS RELATED TO VIOLENT COMMUNICATION AND BULLYING IN KINDERGARTEN

Afrodite V. Ntouka and Panagiotis J. Stamatis*

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

The purpose of this paper is to examine the aggressiveness expressed by preschoolers in kindergarten and is manifested as school bullying. Specifically, this paper aims to record the main bibliographic references of nonverbal and vocal expression of preschoolers in anger situations and how those references are substantiated through surveys. The bibliography claims that school bullying doesn't occur unexpectedly, but there are apparent signs in behavior of preschoolers, that could be prevented before they occur.

This paper aims to record the reasons that positively contribute to the expression of aggressive behavior in preschoolers, the different forms of bullying and its causes. Additionally, they aim to propose indicative methods of treatment. In this way, knowing the causation of an attitude could become easier and more efficient to prevent and efface that attitude. Many researchers conclude that parents and nursery teachers should have to cooperate and constantly communicate with each other in order to significantly help preschoolers who display aggressive behavior in order to change it from becoming a violent one for the rest of their lives. Such conclusions are under consideration and discussion in present study.

Keywords: bullying, preschoolers, kindergarten, nonverbal communication, vocalics

INTRODUCTION

Over the last few years, an intense concern about school bullying has risen among preschoolers, pupils and adolescents. School bullying is directly related to people's inherent

* Corresponding Author's Email: ntouka@me.com.

need for survival, while simultaneously being a feature of human behavior and an element of human nature. Already, since the beginning of human existence, in order to secure the basic needs of life, survival has been linked to the feeling of competitiveness (Donegan, 2012). The term “school bullying” has been established worldwide. Initially, this term was used as a description of aggressive behavior among students. However, nowadays, the term has been linked to violence and delinquency at school (Artinopoulou, 2002). In English, the term “bully” has been in use since 1530 describing the behavior of someone who was trying to scare a weak person. Bullying is the outcome of a bully’s aggressive behavior characterized by violence. According to Bouchard et al. (1996, p. 10), aggressive behavior is defined as “any act which, during an engagement, violates or threatens to violate the physical or psychological integrity of an individual”.. Initially, bullying is viewed as a person’s attempt to impose and dominate over someone else, as a repetitive and systematic act with a variety of harmful actions, such as pushing and destroying personal objects, but also as a deliberate and conscious desire to hurt and oppress someone, either occasionally or in the long run.

At present times, there are numerous definitions for bullying. A common parameter of individual definitions is the assumption that any act of behavior intended to physically or mentally harm the recipient is defined as an offensive act (Dodge, Coie & Lynam, 2007). Despite the fact that there are many similar definitions, all of them conclude that there are specific features of bullying. Those are:

- The existence of motives (intent)
- The impact of the act (pain)
- Duration (repetition)
- Strength (body build, but also family and social background)
- Provocation (provocative victims) (Lee, 2006).

Nowadays, school bullying is a new and modern social problem, which is in need of immediate intervention, in view of its eradication, as it significantly affects the early development of a child. This phenomenon has not occurred recently, but it has already existed since the beginning of mass education. Due to globalization it has sparked interest in recent years. This chapter seeks to present school bullying, occurring in kindergarteners, taking into consideration bibliographical references and surveys that have been conducted on this issue. However, both bibliographic references and studies on this subject are comparatively less than those related to older adolescents. According to studies, in both infancy and childhood, aggressive attitudes, (especially physical) are more frequent, but is gradually decreasing as age increases (Coie & Dodge, 1998). Furthermore, the main forms of school bullying, the causes of the phenomenon and finally, indicative ways of treatment are proposed.

BIBLIOGRAPHIC AND RESEARCH OVERVIEW OF THE PHENOMENON

According to researches, during infancy and childhood more aggressive behaviors are observed, which are dramatically raised during adolescence (Stamatis & Nikolaou, 2016). When children enter school reality, they are called to compete with their classmates, making the best possible school performance. On one hand, this practice introduces them into an

activation and mobilization process to project their best and to demonstrate their abilities, aiming to their superiority within the school environment. On the other hand, this situation produces opposite results, as children use unacceptable methods to characterize themselves in the competitive and social environment, resulting to these methods and practices of intimidation and bullying.

Between the ages of 2 to 5, children have low to moderate levels of aggression, characterized as normal and expected at this age (Alink et al. 2006; Tremblay et al., 1999). However, there is a percentage of 3 10% that will face high levels of aggression over time (Campbell et al., 2006; Broidy et al. 2003). Those children, who show high levels of aggression from a very young age, increase the rates to continue this kind of behavior throughout their childhood, adolescence and into adulthood (NICHD, 2004; Tremblay, 2000).

The first study published worldwide for school bullying was in 1970 by the Norwegian psychologist Daniel Olweus, who also created an intervention program with positive results. According to Olweus (1993; 1991), intimidation is a series of aggressive acts and/or behaviors that take place on a continuous basis and afflict a weak person. School bullying is characterized as a situation in which one student is exposed - repeatedly and for a long period of time - to negative and undesirable acts and situations caused by a student or a group of his or her classmates intended to cause some injury, harm or even negative emotions. All these negative behaviors include, actually, harmful communication processes and are based on violence.

According to Murphy's study, 22% of students are afraid of meeting specific classmates that will bully them. Thus, they avoid being in three or more specific places at school (2009). Also, 5% of pupils are absent from school one or more times a month in order to avoid victimization.

What is more interesting to study and record, is the way infants manifest their aggression, causing school intimidation. School bullying can occur in various forms. According to Coie and Dodge (1998) and Crick and Grotpeter (1995), it can be either physical or verbal. More specifically, physical intimidation can be manifested by bumping, biting, punching, hair pulling and spitting. On the contrary, verbal intimidation - as a more direct and frequent form of intimidation - is manifested through abusive or derisive expressions, with rude comments, ironic, sarcastic expressions, mockery, insulting teasing, nicknames and other attitudes related to violent communication. Violent communication contributes to the development of various forms of aggression and bullying (Stamatis, 2017).

According to Guerra et al. (1995) and Goldstein, Tisak and Boxer (2002), who have studied the phenomenon of apparent aggression at preschool age, this form of aggression is more common. This age is the most appropriate time for early prevention and treatment of the phenomenon so that it does not continue and above all, spread.

What is more interesting, however, is the aggressiveness that takes place non-verbally at this age, yet to be recorded. Moreover, studying the threatening signs that children may be demonstrating at this tender age would be interesting, but above all, the way that their anger is manifested should be recorded. According to Ekman & Friesen, anger is one of the six basic feelings (1971) and according to Russell, anger differs from culture to culture in how it is expressed (1991). However, the non verbal expression of anger can be universally comprehensible, since the pain it causes cannot be overlooked in any civilization.

Most research that has been conducted is focused on the apparent aggression in preschoolers. Apparent aggression is defined as the actions of physical aggression, such as hitting, pushing, biting, throwing objects, kicking and threats to carry out the above operations,

in order to harm a person, using physical expedients (Coie & Dodge, 1998; Crick & Grotpeter, 1995). Apparent aggression is by definition the use of insulting words against another infant in order to cause pain (Goldstein, Tisak & Boxer 2002).

As preschoolers spontaneously, without hesitation and wicked thoughts, express their feelings, apparent aggression increases among preschoolers, compared to other ages (Stamatis, Papavasileiou & Ntouka, 2013). The research conducted by Guerra, Tolan, Huesmann, Van Acker and Eron (1995), and Goldstein, Tisak and Boxer (2002), has shown that children displaying apparent aggression in kindergarten maintain this behavior as they grow, forestalling the difficulties that these children will face later in their social life. The apparent aggression that occurs in infancy does not require the development of linguistic and cognitive skills and thus its manifestation is easily observed (Renouf, Brendgen & Perent, 2010; Bonica et al. 2003).

SCHOOL BULLYING IN KINDERGARTEN

School bullying could not unfortunately leave the area of Kindergarten unaffected. Besides, according to the research of Hasan, Drolet and Paquin, the highest incidence of aggression is at the age of three (2003). Children, after three to four years of exclusive residency at home, are asked to adapt to a new place, away from the family's safety. In the Kindergarten area, they must learn to share objects, coexist with their classmates and participate in group activities, activities that they did not do before. According to Estrela, both the problematic and the disobedient behavior of children are a reaction strategy to the classroom conditions and the behavior of the nursery teacher (1986). In this way, they want to declare their desire for meaningful interpersonal communication with the nursery teacher.

The problematic and the aggressive behavior can greatly influence the smooth development of teaching. Often, such behaviors are manifested by disobedience to the nursery's instructions and the indifference to participate in school activities. Preschoolers express their anger mainly through disagreements, they speak harshly either to their peers or even to their nursery teacher. They purposely provoke with their behavior, being disobedient and irritable. They behave in a hostile way, are willing to destroy various objects around them and they have outbursts of niggling and negativity. They do not ask for permission to talk, but the "pop in" at the nursery's questions, disturbs and interrupts his/her peers when they speak and get involved in verbal debates.

In some cases, preschoolers also express their anger by using nonverbal expressions. In these cases, anger occurs mainly by frowning, tightening or gritting of the teeth and there are cases where anger reveals itself with constant staring on the eyes (Papadaki-Michaelides, 2008). Also, the inner points of the eyebrows are pulled together downwards with the eyes really open and with the lips are either pressed or opened and exposing teeth. In fact, children at this age are quite assertive and react rather strongly if something that they claim is denied to them. At this age they know how to cause pain and harm, regularly using their teeth, wiping and injuring other children, or destroying a toy. They also do not intend to cooperate and participate in collective activities, while trying to disturb other children of the class.

Less interest in attending school is usually observed, or even denial in order to avoid unwanted meetings. Preschoolers who have been bullied, refuse to engage in any activity and are attached to their nursery teacher or other teachers during the break time. In some cases,

preschooler – victims develop psychosomatic problems such as headache and bellyache, without pathological causes. Even preschoolers, who simply observe a bullying episode, feel fear and anxiety, in view of the fear that something similar may happen to them. They also feel guilty, because they did not do anything to help their classmate. Some of these preschoolers may develop bullying behaviors in the future, since they imitate at this age (Stamatis & Nikolaou, 2016).

The nursery teacher may understand that a child is being bullied by other signs. Many times children-victims are characterized by low self-confidence and feel they do not deserve respect and acceptance. These preschoolers often remain alone during the break time and they just observe their classmates. They do not claim objects in the classroom, which is something normal for their age, they show increased introversion and lack of social skills, such as fluency and social discussions (Ntouka, 2017).

There are also signs of aggression, which are considered to be normal at this age. These are signs of the physical aggression of this age, which are eliminated as the preschooler grows. These signs are biting, kicking, stinging, pushing, pulling others' hair and taking others' place on the playground. The most worrying signs are when they pretentiously mock, reveal others' secrets, exclude their peers from plays, collective games and activities, use nicknames and finally the embarrassment of public humiliation (PrevNet).

However, aggression is often confused with disobedience, opposition and contradiction. Preschoolers usually become disobedient when they are tired, stressed or upset, which are situations that are part of the normal maturation of preschoolers. Nevertheless, when disobedience evolves into frequent objections and contradictions, it can arise problems in relationship among the preschooler and their nursery teacher, their classmates and their parents, but also to themselves and gradually develop intense aggression which will lead to school intimidation.

On the other hand, aggression can be expressed in two forms, the direct and indirect - element aggression. As direct aggression is defined as hostile aggression that deliberately hurts others, validating its dominance. Preschoolers express their aggression because they want to hurt their peers and in general they have an aggressive attitude. Indirect - element aggression is defined as the situation in which a preschooler provokes indirect harm to other preschoolers while trying to acquire and mention exclusive sovereignty over an entitlement or object, such as a toy (Cole & Cole, 2001).

According to Hinshaw et al. (1992), a preschooler's school performance is associated with attention and academic performance problems in elementary school. It can also be associated with antisocial attitude and behavioural disorders.

SCHOOL BULLYING FORMS

There is no universal manifestation of school bullying. On the contrary, it can obtain a variation of forms. According to Rigby, there are three forms of school bullying, which can take place either directly, through the interpersonal contact of the victim and the victimizer, or indirectly, without any personal conflict (2005). Those three forms are verbal bullying, physical bullying and the use of gestures. Verbal form of bullying takes place with the use of offensive vocabulary, the use of nicknames, humiliation, hideous teasing and intense mockery. Indirect

verbal bullying happens by introducing a third person to insult or even exploit another child. Spreading false rumors, making anonymous phone calls with offensive vocabulary, sending threatening messages, etc. are some expressions of indirect verbal communication bullying (Stamatis, 2017). The direct physical expression of bullying involves physical attacks by kicking, spitting and throwing objects, while indirect physical expression takes place by deliberately and unfair exclusion of their classmates from activities, as well as abduction and hiding personal belongings. Lastly, the direct expression of school bullying through gestures involves threatening moves and persistent glances, while the indirect expression of this, involves the repeated aversion of the person or gaze, in such a way that the child - victim may feel as an intruder.

International literature makes the following divisions of school bullying:

- *Verbal*. It is one of the most direct and common forms of school bullying. It includes the use of abusive and mockery expressions, nicknames, threats, teasing, rude and ironic comments, etc. However, it is a form of bullying that is difficult to be settled, as there is not enough accumulative evidence, but only testimonies by attendees (Van Niekerk, 1993).
- *Emotional*. This is an indirect form of bullying, including threats and extortions, the spread of false and unsubstantiated rumors, and even derisive comments for a child's nationality, race and religion. It also includes the deliberate distancing of friends and isolation (Neser et al., 2003).
- *Psychological*. It is also an indirect form of bullying where child-victims repeatedly and deliberately experience exclusion from social and group activities and exclusion from games during the break time. Similar to the emotional bullying malicious remarks and mockery of the victim(s) are taking place (Krige et al., 2000).
- *Physical*. This is the most direct form of school bullying, involving physical violence, bumps, bites, strokes, theft of personal property, etc. This form is directly related to muscle strength and the physical build of the child – victimizer. For this reason, smaller children are often being bullied by children from older classes (Leach, 1997).
- *Social*. In social bullying children are intentionally excluded from social activities and this kind of bullying may be either direct or indirect. The former refers to the systematic exclusion, indifference and isolation of the victim, while the latter is perceived by the victim only if they attempt to participate in any group (Coloroso, 2003).
- *Racist*. In this form, bullying is expressed verbally, emotionally or physically. The main purpose of this kind of bullying is the victim's insult due to either the origin or social class or the financial situation of his family. It generally refers to the difference between the child - victim and the majority of the children.
- *Bullying with bullying*. Another form of bullying that occurs in kindergarten and is expressed by destroying the victim's material objects and by detaching his/her objects. Those actions are accompanied by threats and extortions and by forcing them to participate in undesirable antisocial acts (Tsiantis, 2008).

- Finally, there are also *cyber* bullying and *sexual* bullying, two forms of bullying that do not fall within the research interest of this article, since they appear extremely rare in kindergarten.

CAUSES OF SCHOOL BULLYING

An important parameter is also the recording of the causes that provoke the aggressive behavior of preschoolers. Some of these causes are:

- Potential family problems and/or changes: financial problems, divorce, removal, bereavement, even the birth of a new member.
- Pursuit of attention: preschoolers seek the attention of either their parents or nursery teachers in any way, which may even be an aggressive act.
- Imitations of standards: the family, school and social environment with which the preschooler is in contact, comprise (constitute) the institutes from which the preschooler will copy and adopt patterns and behaviors.
- Psychological characteristics of preschoolers: the personality of each preschooler plays a key role in whether they will receive school bullying or not.
- Social and Cultural Criteria: preschoolers are often the most rigorous judges, targeting children of lower social class with obvious changes in their appearance, as well as children of different cultural groups.
- Lack of participation in extracurricular activities: children often suffer from intense anxiety, which is vented into their classmates, if this anxiety is not decompressed in creative activities.
- Gender: the victimizer is usually a boy.

Thus, it seems that preschoolers express their anger in order to avoid painful situations and feelings that may be caused by low self-esteem, isolation, anxiety and failure, i.e., situations in which preschoolers do not have any control. Also, the outburst of anger can be a result of regret or even depression.

INDICATIVE METHODS OF BULLYING TREATMENT

Often, many parents and preschool teachers who interact with aggressive preschoolers wonder about the methods and ways in which these children could be supported, by limiting and eliminating those behaviors. Initially, the primary concern of those who wish to help is to honestly want to help and not to punish the child. Also, any positive action of the kids should be welcomed and strengthened, ignoring and not commenting on their negative and bad behavior.

Nursery teachers, as the first persons who will observe an aggressive episode, should immediately intervene. They should try to strengthen the self-confidence of a child-victim and

to develop strategies which will help those children. They should also design a personalized approach plan with alternative approaches, such as paintings and role-playing games, in order to express their feelings and anger in a health way. They should try to strengthen friendship and solidarity among classmates and discuss with the children about the appropriate ways of verbal and nonverbal expression, thus preventing any aggressive behavior.

An essential role is also played by the effective contact with the preschoolers. A touch or a friendly pat on the back are capable of positively boosting the preschooler and giving him the attention he/she needs. Also, verbal expression of preschoolers should be enhanced to discuss their feelings and problems by avoiding negative behaviors. Even setting limits is a positive practice of helping preschoolers effectively, while parents and nursery teachers should be positive role-models for children.

The collective organization of the class and the collective formulation of rules for routine procedures may also play a positive role in the prevention of the phenomenon. The preschool teacher should still try to actively involve these preschoolers in the learning process and develop positive interpersonal relationships in the classroom. Creative preoccupation of preschoolers, either by building a visual work or by preparing a theatrical performance, can positively influence the behavior of more aggressive preschoolers.

Finally, the active involvement of the preschoolers' parents and their good communication with preschool teachers, is a vital part of the effort to reduce or even eliminate school bullying. Parents should be actively engaged in the educational process; for instance, by developing seminars and lectures as speakers on topics they know and which may be about their profession, personal interests or even their talents.

CONCLUSION

It should be said that the preschool age is the most appropriate age for early prevention, recognition and dealing with the phenomenon of school bullying, so as to avoid perpetuation and its deterioration (Rubin et al., 2003; Denham et al., 2002; Huesmann & Moise, 1999; Loeber & Stouthamer-Loeber, 1998). According to Walker, Colvin and Ramsey, an intervention program, which is appropriately designed to reduce and eliminate the phenomenon, is more likely to have an effect if it occurs until the age of eight (1994). If it is not resolved until this age, preschoolers run the risk to grow and become part of antisocial and delinquent situations.

In conclusion, there are preschoolers in need of help rather than be labeled "bad" preschoolers. All of this aggressive behavior that manifests and leads to school bullying, is the result of interactions within their environment, while combining their individual characteristics. What should be said and comprehended is that each preschooler is a separate case and needs to be assessed by a personalized intervention program. Not all behaviors should be treated in the same way, nor do they show aggression in the same manner. Nonviolent communication is considered to be the key of bullying control in every educational environment, and even more in kindergarten. The way that preschool teachers and parents talk to preschoolers, accompanied with the nonverbal behaviors and attitudes they show to them, is very critical for their present and future perception about bullying behaviors and the consequences it has to themselves and others. Treatment of such behaviors should be an educational target and the whole school unit

should deal with it collaboratively. The prevention and intervention techniques of such problematic situations should be used systematically, rather than being treated fragmentarily when aggressive behavior is already shown.

Chapter 28

CLASSROOM NOISE AND MISCOMMUNICATION AS MODERN FORMS OF VIOLENT COMMUNICATION AND BULLYING

Panagiotis J. Stamatis*

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

Classroom noise is a key parameter of teaching efficiency and learning because it is related to the classroom climate. On the one hand, the teacher's request to teach in a calm environment without being disrupted by noises of any origin, and on the other hand the students' right to attend the lesson in a quiet environment without voices and other distracting noises, are fundamental factors for ensuring qualitative and effective teaching. Over the course of time, the issue of classroom noise has raised concerns among teachers and the global academic community, which has scientifically and thoroughly highlighted its dimensions and negative effects on educational, psychological and biological aspects. This paper discusses the implementation of communication rules in a kindergarten can gradually achieve noise reduction in the classroom by eliminating miscommunication and para-communication. Kindergarten teachers and parents of early childhood children in expressing their views on this issue claim that communication rules should be implemented in early childhood classrooms especially during the teaching processes. Similarities and differences regarding to teachers' and parents' opinions are discussed, to better understand context in which both educational partners are going to establish a collaboration for addressing the problem.

Keywords: classroom noise, miscommunication, violent communication, bullying, kindergarten, early childhood, communication

INTRODUCTION

A few decades ago, teacher-centrism was a prevalent teaching process, some pedagogues, inobserving the classroom climate compared the classroom conditions to those of a “cemetery,” due to the total silence on the pupils’ part. Only the voice of the teacher who was constantly speaking could be heard, in his/her attempt to explaining the lesson in several tones of his/her voice, that is, by shouting, threatening or even insulting the students while trying to create and maintain a sense of order in the classroom. Whenever such behavior was inadequate, the teacher’s attempt was reinforced by corporal or other forms of punishment. Students did not dare to speak in the classroom without teacher’s permission. They were just silent attendants, listening to the speaking teacher without asking any questions for clarification or expressing their thoughts and feelings. Despite a few exceptions, this teaching climate prevailed for many centuries.

After a change in our perceptions regarding teaching, and with the prevalence of paidocentrism, the teaching climate changed completely, it was almost transformed. Pupils are thus encouraged to speak in the classroom during the teaching process in order to express their views, ask the teacher questions, or communicate with their classmates in the context of collaborative projects, etc. As a consequence, in the contemporary educational system, the role of the teacher has changed. It has become peripheral rather than central and quite different from what it traditionally was. The modern teacher organizes the teaching process, animates and guides pupils in order to facilitate the discovery of knowledge (Wong et al., 2014; Marzano, Marzano & Pickering, 2003).

Today, in most Western and Eastern countries, more and more students of all ages are encouraged to actively participate in the teaching process. More specifically, students are encouraged to speak, ask and express themselves rather than silently participate in instructional sequences. In short, they are encouraged to become active rather than passive attendants of what is taking place in the classroom. In some countries, children are trained from a very young age to acquire social and communication skills in order to render the learning process more effective and develop excellent interpersonal relationships in the future (Simon & Coopers, 2011; McCroskey, Richmond & McCroskey, 2006). As some surveys have shown, children with acquired social and communicative skills, generally show better academic performance than children without them (Linsin, 2013). Also, children with developed social skills become more acceptable and beloved by their teachers and classmates; they are more assertive and get less involved in situations of conflict and bullying (Stenberg & Williams, 2009).

Consequently, due to modern perceptions, schools no longer resemble a quiet cemetery but rather a bustling beehive, where, although countless bees come in and out and work incessantly, each of them undertakes the proportionate work in the most effective way, without bothering one another and raising any problem. Does this situation also apply to modern classrooms or does the generated noise by the communicative teachers and children disturb and create various problems during the teaching process? Does the lack of communication strategies, the avoidance of implementing communication rules in the school classroom help create an “anarchical framework” of communication which fosters misinterpretation, inconsistency and ultimately a modern “communicative Babel,” a communicative chaos within the classroom and education in general? In case this is true, with what educational dimensions can it be related and what problems can be raised within the school and its external environment as well?

Does communication confusion “fit” to the modern teaching processes and learning principles? Does this situation match the contemporary teacher’s role and educational objectives? Can the unregulated ability to communicate in the classroom be considered as a useful pedagogical strategy appropriate for the 21st century school or rather a modern form of para-communication which ultimately turns against both educators and pupils or even against education itself? Is it now high time the issue of communicative bullying was openly discussed as a covert form of verbal and nonverbal violence which helps develop aggressive or fearful personalities by promoting undemocratic perceptions in an indirect way, even in children of early childhood? This paper attempts to provide answers to the above questions, based on a relevant literature review along with an empirical study conducted in kindergartens.

BASIC PARAMETERS OF TEACHING CLIMATE FORMATION

The quality of the classroom climate is one of the most crucial factors contributing to the effective implementation of teaching strategies. Numerous relevant studies have highlighted the importance of this factor, stressing, as they did, the key role of interpersonal relationships - a positive contributor to the good climate in the classroom, in the case of both successful teaching and academic performance. Studies also report some additional aspects positively affecting the classroom climate such as appropriate teacher’s preparation, content, form and structure of subject matter, educational material’s suitability, physical arrangement of the classroom, and the teacher’s behavior in general, age and the readiness of students to attend a specific school subject, school culture, number of students attending each classroom, educational framework according to legislation, etc. The aspect of discipline within the classroom should also be considered, both during the development of teaching activities and pupils’ work (Nelsen, Lott & Glenn, 2013; Berg, 1987).

In school units where organization is not a fundamental prerequisite for the qualitative implementation of teaching and educational work, as is the case, for example, in many developing countries around the world, where, in the name of populist views about progressivism and democracy, discipline during the teaching process is considered to reflect a “fascist” perception that aims at oppressing children and transforming them into fearful and subdued personalities. Even the word “discipline” has been incriminated in terms of the educational language, as an obsolete word almost identical to the concept of fascism and anti-democratic perceptions. One could reasonably wonder at which point discipline and organization turn into negative concepts aspects for education. On the contrary, most surveys show that education without discipline and organization would provoke much more problems (Canter, 2009).

Concepts such as classroom management, classroom discipline, classroom assessment, discipline problems, etc. are key words for developing a variety of theories, teaching strategies and techniques for classroom’s control and ultimately for the improvement of interpersonal relationships in the classroom and the development of the social skills of self-discipline and broader discipline related to all commonly accepted rules inside and outside the classroom (Wong et al., 2014). Relevant studies have shown that effective classroom management results in positive outcomes for both pupils and teachers as it establishes and maintains an orderly classroom environment, increases meaningful academic learning and facilitates social and emotional development of children (Emmer & Sabornie, 2015; Crone, Horner & Hawken,

2004). Furthermore, effective management reduces negative behavior like disciplinary problems and increases time spent specifically for academic purpose. Chaotic classroom environments are a great issue for teachers and can contribute to high teacher stress and burnout rates, especially when there is no access to support by specialists, within work environment. Such specialists can be school psychologists, special education teachers, school counselors, school head masters and parents (Slavin, 2014; Brophy, 2006).

Despite discipline and respect for rules, an effective teaching process requires quietness, order and a constant focus on what is said and done in the classroom. When this is not the case, that is, when pupils are indifferent and get distracted during the lesson, the teaching process gets interrupted. Thus quietness and pupils' attention are absent from the educational process. In case pupils speak any time they want to with their classmates and mock each other, then the teacher has to intervene, setting aside the teaching activity. If teachers know how to manage such situations, they can restore peace and quietness, otherwise tension may increase, irritation can be created, the teaching process may get interrupted and the teaching process will probably fail leading to disappointed and frustrated teachers. Therefore, the level of classroom peace, which depends on the noise intensity during teaching, plays a vital role in teaching quality, good classroom climate development and, hence, effectiveness. Noise and disorder in the class favor the development of communication aggression, communicative violence, miscommunication and a climate which feeds school bullying. Not only is communication an extremely unpleasant situation that drastically inhibits the development of mutual understand and cooperation among the members of a working group, but it also contributes to conditions of rivalry, aggressiveness and conflict among pupils and/or teacher in the classroom environment.

CLASSROOM NOISE: A LITERATURE AND RESEARCH APPROACH

Noise is generally defined as unwanted sound since it can be perceived as unpleasant or bothersome; it interferes with activities or can even be physiologically harmful in a way (White, 2016). Noise is produced within the classroom where almost twenty five (25) pupils and a teacher are all working together with modern teaching methods much different from the traditional lecture-based methods. Nowadays, teaching methods focus on problem-solving. Students must be more interactive and work in groups during projects, thus, modern teachers should change their traditional role towards the one of a supervisor, guiding not lecturing (Boothroyd, 2011). Due to these changes most of the noise is likely to originate from human activities such as chatter and laughter and moving chairs and tables. Classroom noise is always a serious problem during the teaching process. A specific type of noise exposure in the classroom is produced by footsteps, chairs, tables, doors and building structure (structure-borne noise). Noise may be caused by indoor and outdoor sources, affecting pupils' and teachers' behavior (Landström et al., 2002).

Research has additionally proved that teachers working in classrooms with louder ambient noise, speak louder than those with lower noise levels. Voice varies generally less among teachers working under loud activity noise than others under lower noise levels. Ambient and activity noise affect teachers' voice use. Teachers seem to speak habitually loudly under loud ambient noise and their ability to react deteriorates under loud activity noise levels (Rantala, Hakala & Sala, 2015). Furthermore, it seems that noise can have detrimental effects upon

children's performance at school, including reduced memory, motivation, and reading ability. External noise was found to have a significant negative impact upon performance, with greater effect on older children (Shield & Dockrell, 2008). Children get particularly influenced by the noise generated by individual external events. Another research suggests that quieter noise can have varied effects upon students' learning and memory since low-level classroom noise distracts pupils' concentration from what teachers say (Sparks, 2015). Consequently, neither high-level classroom noise nor low-level one is suitable for effective teaching. Thus, a medium-level classroom noise might be more appropriate.

Classrooms are learning environments where children gather more than 70% of information through the process of listening alone (Pellow, 2004). Thus, it is not surprising that the better the listening to the teacher, the easier the learning. In classrooms around the world, noise has been identified as a problem for most pupils and teachers. As stressed in many related studies, when classrooms are too noisy there is a negative implication on effective communication among pupils and the teacher (Blake & Busby, 1994). In fact, if the background noise is louder than teacher's voice, it can sometimes render listening and learning very difficult especially for children with hearing impairments and learning disabilities (McLaren & Dickinson, 2009). Children's brains are not fully developed in terms of listening until they reach their early teenage, so early childhood pupils find it much harder to hear and understand their teachers especially when their voice gets mixed with various classroom noises. Contemporary teaching methods, namely group work and incidental learning, contribute to noise levels increase in the classroom as mentioned above. Open-plan learning can cause problems for all children, regardless of their hearing ability. Noise can interfere with concentration and speech perception, impairing educational outcomes. Research shows that young children need a quieter setting than adults in order to recognize speech. They cannot properly develop basic literacy and numeracy skills within an environment where they miss hearing key words, phrases and concepts.

Classroom acoustics interfere with effective communication along with hearing protection which is vital at a young age, to avoid a hearing crisis in the future. Thus, school architects must design or renovate classrooms in such a way so as to provide good listening conditions and regulate classroom noise. The best way to solve acoustic problems is prevention. During the design process, acoustic problems can usually be avoided with a bit of forethought and different building materials arrangement. Renovation of poorly designed classrooms is much more expensive. To protect children from all types of classroom noise teachers should better:

- Add acoustic surfaces. By placing carpets on the floor and acoustic tiles on walls, particularly on the ceiling, teachers can achieve impressive results related to noise and classroom sound quality control.
- Create some quiet zones. By using mats, removing tables and other sound-reflecting surfaces, hanging heavy curtains or replacing common windows' glasses with double glazing, noise-resistant zones can be formulated to protect classrooms from external noise.
- Manage the "café effect." Café places are too noisy as people speak loudly all together in an attempt to hear one another. In contrast, in the classroom everybody must speak quietly in the classroom so that they can all be pleasantly heard by their communication partners. Teachers should get children's attention by speaking calmly and quietly and

similarly, pupils have to be quiet so they can hear the teacher. Teachers must be informed about the benefits of quietness not only in the classroom but in the home as well.

- Adjust the program. Teachers may restrain from active and noisy teaching activities and adopt quieter ones explaining the benefits of speaking quietly and quietness at school and home.

The discussed issues of classroom acoustics are relevant throughout the world, so the claim of Berg, Blair and Benson (1996, p. 16) can perfectly sum up the existing literature: “classroom acoustics are generally overlooked in American education. Noise, echoes, reverberation, and room modes typically interfere with the ability of listeners to understand speech. The effect of all of these acoustical parameters on teaching and learning in school needs to be researched more fully. Research has shown that these acoustical problems are commonplace in new as well as older schools, and when carried to an extreme, can greatly affect a child's ability to understand what is said. The precise reason for overlooking these principles needs to be studied more fully. Recently, however, acoustic principles have been clarified, and technologies for measuring room acoustics and providing sound systems have become available to solve many of the acoustical problems in classrooms. Solutions are noise control, signal control without amplification, individual amplification systems, and sound field amplification systems.”

PURPOSE OF THE STUDY

As Dreossi and Momensohn-Santos (2005) have stressed that “a lot has been spoken about noise, sound pollution, psycho-physic alterations in the human being due to the noise and, therefore, a lot of school professionals have been asking about the noise impact over the day-by-day educational activities developed in the school. Several mass communication means, such as newspaper, magazines, have published in their articles discussions and approaches about the disorders provoked by the noise on people who are daily in contact with noise. Most interestingly is that we don't even notice that we live with moderate noise daily and that it becomes our body's enemy. We can realize that even during pleasure activities we are exposed to strong intensities of noise and that people assume a passive posture, seeming not to be aware of its harmful effects and to avoid it.”

Within this framework and considering the fact that not adequate research into classroom noise in early childhood classrooms has been conducted, this study aims to investigate the opinions of kindergarten teachers and parents of preschool age children about the possibility or necessity of communication rules implementation during teaching activities. In this way it is expected that classroom communication will improve while miscommunication and para-communication among pupils and the teacher will diminish, resulting in high teaching quality standards. Any classroom without communication rules seems like an unorganized context where communication violence and communicative bullying can easily develop.

METHOD

This study was conducted in Greek public kindergartens, situated in different prefectures of the country. It commenced in October 2015 and was completed in January 2018. The study

was conducted within the framework of a research course titled: “Forms of communication in kindergarten: Psycho-pedagogical dimensions.” The course takes place during the winter semester in the Department of Sciences of Preschool Education and Educational Design of University of the Aegean under the surveillance of this paper’s author. The students who attended this course undertook the gathering of the present study data. The *sample* of the study consisted of one hundred and twenty (120) early childhood teachers and two hundred and twenty five (225) parents of children in early childhood. Most of the teachers who participated in the study had mainly teaching experience of twelve (12) years. The majority of them were women aged 36-40 years old. Most of the parents were mothers (N=198, 88%) aged 31-35 years old, housekeepers of middle-level education. The majority of fathers (N=27, 12%) were among 36-40 years old, middle-level educated and employees in private sector.

Teachers and parents were provided with a common questionnaire/statement sheet which was actually the main *data collection instrument*. It was designed by the researcher/author of this paper and consisted of thirty six (36) closed-ended questions/statements in total. Eighteen (18) of them were related to the expressive/spoken communication behavior of a child, seven (7) were related to the audience/listening communication behavior and eleven (11) were related broadly to communication behavior of the child inside the classroom. All statements dealt with a communication rule that could be implemented by pupils in the classroom, especially during the teaching process and activities. Some additional data related to personal traits of the sample was required. For the participating teachers this kind of data involved the gender, age and years of teaching experience. For the participating parents such data included the gender, age and number of children. The statement sheet is presented below in Table 1. Participants could choose between two choices, Agree (A) and Disagree (D), to express their opinion. All the answers were confidential.

Table 1. Communication Rules in Early Childhood Education – Statement sheet

Additional data for teachers and parents

Tick (✓) the appropriate empty square below:

Teachers												N=120
Gender	M	0	W	120								
Age	25-30	0	31-35	12	36-40	85	41-45	15	46-50	8	51-55	0
Teaching Experience	0-5		6-10	15	11-15	93	16-20	12	21-25		25-30	0
Parents												N=225
Gender	M	27	W	198								
Age	25-30	32	31-35	159	36-40	25	41-45	7	46-50	2	51-55	0
Children	1	46	2	141	3	28	4	8	5	2	6	0

During the *data collection stage*, the university students kindly asked from teachers and parents to voluntarily complete the questionnaire/statement sheet explaining them the purpose of the study, its significance, and procedure details without asking for the participants’ name as it was not required. The completion of the sheet was scheduled to take approximately 10 minutes, so as the participants would show undiminished interest while completing it. Participants could choose to complete the statement sheet either outside the kindergarten place

or at home, returning it to the students on the next day. Participants had the alternative to receive the statement sheet via email in order they have plenty of time for thinking about each statement content and provide an appropriate answer without time pressure.

36	not be furious without any important reason, not either hit or ever swear any child even when furious.	89	11	82	18

RESULTS AND DISCUSSION

Table 1 presents certain percentages which depict relative frequencies. These percentages analytically refer to the total results of the responses given by the participants in the current study (nursery school teachers and parents) about a number of issues to be introduced and implemented as communication rules in nursery classrooms. The interpretation of these percentages could lead to interesting conclusions regarding the introduction of specific communication rules in Greek public kindergartens. The present study has mainly exploratory and diagnostic character examining the views of nursery teachers and parents about issues related to communication behavior of preschoolers and the context of communication in a nursery classroom in general.

The study has shown that almost the overwhelming majority of kindergarten teachers agrees with the implementation of the proposed communication rules concerning all three levels of investigation, namely expressive/spoken communication behavior, audience/listening one and broad communication behavior of a child developed within the classroom. Most of parents seem to agree with most of the views expressed by kindergarten teachers. The views of nursery teachers about issues related to communication of preschoolers inside the classroom are expected to be more objective than parents' views as the former are mainly shaped due to the experience acquired in classroom. Parents' views are primarily shaped by their desires and expectations which are subjective factors, taking also into consideration the sensitive nature of early childhood education in the nursery classroom experienced possibly for the first time in their lives. Within this framework, the comparison between the two groups of participants, that is between teachers and parents cannot produce reliable results. However, the comparison of their responses with the provided percentages of Table 1 can illustrate the most dominant trends within both groups.

During the results' interpretation phase, it was observed that kindergarten teachers and parents agree strongly or very much with most of the statements and the percentage difference between them does not exceed 10%. For some statements, for example 17 and 20, a complete agreement was recorded. In several other statements, such as 6, 7, 11, 12, 13, 19, 22, 24, 25, 26, 27, 28, 30 and 32 the percentage difference ranges from 1-5%. This means that a high-level agreement exists between teachers and parents with those statements. All the above-mentioned cases indicate that the corresponding communication rules are mutually accepted almost at an absolute level and could therefore be easily and directly applied in the nursery classroom. Regarding some statements, teachers and parents disagree at a moderate level as the difference between their statements varies from 6-10%. Statements 3, 4, 5, 21, 23, 31, 33, 34 and 36 are included in this case. In all other statements, namely 1, 2, 8, 9, 10, 14, 15, 16, 18, 29 and 35, the difference is higher than 10%. This means that more dialogue and actions are needed to bridge the gap between teachers' and parents' opinions. The slower this happens the slower classroom's communication framework gets regulated for a good classroom climate, while noise, mess and communicative bullying increase.

As a significant number of studies indicate (Linsin, 2013; Stenberg & Williams, 2009), cooperation between teachers and parents is the most important factor in addressing modern educational problems. The same factor plays a vital role in dealing with noise inside the classroom by establishing and, above all, implementing mutually acceptable rules of communication behavior. Children should learn from an early age that they must respect and therefore abide by fundamental communication rules, especially at home or within school environment (Senechal, 2012). If this happens, teaching conditions will get improved and become more humane and social, leading to a gradually more effective, meaningful, fruitful and reliable education.

CONCLUSION

Classroom noise during the teaching process, when deliberately created by teachers and students, contributes to communicative violence, because if it takes place in a violent way without consent, it removes, deprives or cancels the right to freely express opinions and/or emotions. When a child deliberately produces noise in the classroom during the teaching/learning process, with the purpose of interrupting the teacher or distracting the classmates, this annoying behavior is equivalent to exercising communicative violence that offends pupils, harms classroom climate quality and reduces the quality and effectiveness of the educational work.

Bearing in mind the above-mentioned framework, kindergarten teachers and parents agree to an extremely large extent that the implementation of communication rules in the nursery classroom is pedagogically necessary. The present study specifically provided evidence that teachers and parents totally or almost totally agree that a child in the classroom during the teaching process, regarding expressive/spoken communication behavior rules implementation should: 1) speak after s/he raises a hand for receiving teacher's permission and then ask whatever s/he wants to know, 2) not say something that will annoy/harm another child/children, teacher or parents and 3) know that s/he is not allowed to laugh loudly. Within the context of audience/listening communication behavior rules implementation a child should: 1) listen

carefully to what is being said at any time by the teacher, classmates or parents and 2) not laugh all the time when s/he communicates with another person. Within the context of broad communication behavior rules implementation a child should: 1) show respect and think very well whether to provide an answer or not for a question and 2) know that collaboration with all classmates and non-verbal expression of feelings without sarcastic laugh are very important.

Moreover, from the study's results it was shown that teachers and parents agree at a high degree (very much) that a child in the classroom, regarding expressive/spoken communication behavior rules implementation should speak calmly, quietly, courageously and politely. Within the context of audience/listening communication behavior rules implementation a child should: 1) look every time straight in the eyes the person who officially speaks in the classroom (teacher or another pupil) and 2) think carefully about what classmates say. Within the context of broad communication behavior rules implementation a child should: 1) laugh when s/he listens to something hilarious but 2) not laugh without any reason during teaching. On the contrary, a child should 3) be quiet and not bothering, 4) not be furious without any important reason and 5) not either hit or belch any child in case s/he becomes furious.

As it can be seen by the provided statements of the participants (i.e., teachers and parents) of this study, they strongly disagree that a child in the classroom, regarding expressive/spoken communication behavior rules implementation should only speak when appropriate and when his/her turn comes to speak. On the other hand, a child should ask further questions for anything s/he does not fully understand, say what s/he believes slowly and clearly and express what s/he feels slowly and clearly knowing that mocking, reviling and saying "bad" words are not allowed. Teachers and parents also disagree that a child should feel ashamed and fearful whenever s/he is going to speak. Moreover, there is a dispute about a child's right to scream. Regarding audience/listening communication behavior rules implementation, no disagreement has been noted. Finally, within the context of broad communication behavior rules implementation a child should know that it is important to do what his/her teacher asks in terms of the teaching process, and should not be stubborn attending the lesson all the time.

The views expressing an agreement with the questionnaire's statements indicate that most of the proposed communication behavior rules are acceptable and quite ready to be implemented in early childhood classrooms. Those expressing a disagreement imply that more discussion and further research is needed to understand the real reasons leading teachers and parents to disagree on some classroom communication issues. As mentioned above, classroom noise creates miscommunication and para-communication which constitute hidden bullying forms of modern education. An agreement on the part of both teachers and parents with all proposed communication rules shown in table 1 and their implementation in kindergarten classrooms especially during the teaching process will probably assist on addressing bullying in early childhood. As it is well known, teacher-parent collaboration is considered extremely crucial nowadays not only for addressing violent communication and bullying but also other educational issues, including teaching activities. Teacher-parent collaboration is essential especially for kindergarten effectiveness.

LIMITATIONS AND FUTURE RESEARCH

Despite the relatively large sample of the present study, there may be some limitations as the study is based only on perceptions of teachers and parents who share common culture

elements. Classroom observation in real time is estimated that could positively contribute to further findings and concluding statements as well. The strengths of this study are obvious. Based on previous relevant studies it provides further information regarding classroom noise and its impact on classroom communication, interpersonal relationships among teacher and/or pupils, classroom interactions, and teaching effectiveness. As the study focuses on early childhood communication behavior, useful information about how children and teachers perceive noise in the classroom is gathered for communication rules implementation, regulating classroom behavior of pupils and reducing classroom noise along with all negative kinds of behavior connected to such noise. Communicative bullying is considered the most serious one.

ACKNOWLEDGMENTS

Cordial thanks to early childhood education teachers and parents who voluntarily and willingly participated in this study. Their participation contributed to the realization of the purpose of the present study in the best possible way. Sincere thanks are also due to all students of the Department of Sciences of Preschool Education and Educational Design, University of the Aegean, Rhodes-Greece, who participated in the research courses during academic years 2015-2016, 2016-2017 and 2017-2018. Their contribution to the research data gathering was crucial. Many thanks to Dr. Ioannis A. Paizanos and Professor Ioannis (Yannis) Hatzigeorgiou for their assistance in editing this chapter.

Chapter 29

OBSERVING KINESICS OF VIOLENT COMMUNICATION AND BULLYING IN EARLY CHILDHOOD CLASSROOMS

Panagiotis J. Stamatis* and Kyriakos A. Marousis

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

Early childhood studies and teachers' reports show an increase in violent behaviors and bullying in the classrooms. This phenomenon is of interest to researchers and early childhood teachers who seek to ensure and maintain a safe and functional classroom environment. It is crucial for the researcher to identify, capture, and analyze the nonverbal violent signs that may occur in the classroom, while it is important for the early childhood teachers to be able to identify and prevent these behaviors from happening. This theoretical study underlines the need for observing nonverbal violent communication and bullying related to kinesics as an essential step for addressing these issues. This study discusses observation planning, several methods and techniques of observation, the proper means of analyzing data, and finally, the documentation of these findings.

Keywords: observation techniques, nonverbal communication, kinesics, coding systems, violent communication, bullying, communication

KINESICS, NONVERBAL VIOLENT COMMUNICATION AND BULLYING: AN INTRODUCTION

According to Vrettos (2003), neither verbal nor nonverbal communication channels suffice on their own. Nevertheless, in this paper, the focus is on the characteristics of communication,

* Corresponding Author's Email: stamatis@rhodes.aegean.gr.

rather than on its content. Communication within the classroom may be either formal or informal (Cosmopoulos, 2006). As analyzed by the clinical psychology professor Robert Mellon (2002), non-verbal communication is broadly defined as any type or form of communication other than words. Thus, from a psychological point of view, the production of communication requires the exercise of all parts of the human body and not only the utterance of verbal symbols (Wylie, 1985). Correspondingly, Cormier and Cormier (1985) note that all parts of the body are required to transfer emotions and behaviors. Furthermore, in a multidisciplinary approach to psychology and education, both behavior and feelings are key features of the learning process, as analyzed in emotional intelligence (Cook, Greenberg & Kusche, 1994).

Preliterate children are right-brain dominant and only switch to left-brain dominance as they develop writing and reading skills. A child who is able to understand nonverbal signs during infancy, develops a wide range of vital social skills (such as making friends) by correctly interpreting the expressions and gestures of their classmates. This demonstrates the importance of nonverbal communication to the acquisition of verbal proficiency. Nonverbal communication is learned well before the process of verbal communication (Miller, 1988), including expressive signs, signals, cues, and hand gestures. It aims at going beyond simple verbalization into a communication process that regulates and enables a more holistic flow of interaction amongst individuals (Trehnolm & Jensen, 2008). Moreover, 93% of face-to-face communication is nonverbal (Mehrabian, 1968), whilst about 70% of the information communicated during a conversation is conveyed by the expressions and gestures we use to accompany our words, meaning that we can communicate both verbally and non-verbally at the same time. Nonverbal communication is exhibited either consciously or unconsciously. For example, actions such as winking are learned, whilst others like blushing are innate (Zoric et al., 2007). Nonverbal messages and actions are considered to be more genuine and deception-free, as they are used to express feelings which may otherwise be too disturbing, or more uncomfortable to share (Miller, 2005). Due to their communicational limitations in early childhood, children express their feelings, emotions and behaviors nonverbally with body language. According to Wallbott (1982), kinesics could provide legitimate data about social actions, emotions and interpersonal behavior, as opposed to other functions. Observation seems to be the key element in order to understand children's development stage and their well-being (Palaiologou, 2016).

When it comes to the classroom environment, it is of great significance for an educator to be able to notice and understand a student's nonverbal cues, as unconscious actions and reactions portrayed by the children are manifestations of statements that they feel and are unable to otherwise express. According to Stamatis (2005), nonverbal communication in children of early childhood, seems to be the primary and more direct channel of communication. Via parent/teachers' nonverbal communication, young children are provided with body language blueprints upon which they draw in order to develop many of their own nonverbal communication skills. By encouraging the use of such skills, it is ensured that the child uses body language regularly and fluently, which is ultimately fundamental for the growing child's social success (Lewis, 2015).

Language and social skills are crucial in typical early childhood development. Indeed, non typical development in these areas may be a warning sign for aggressive behavior later on (Jenkins, Mulvey & Floress, 2017), such as alienation from peers, and other problematic behaviors (Miles & Stipek, 2006). Foundational social communication skills –involving both

verbal and nonverbal communication—typically develop during preschool years through social reciprocity with caretakers during the first two years of life (Owens, 2012). In the classroom environment, at this stage of development, verbal communication will primarily evoke cognitive meanings for the student, whereas the more pervasive, nonverbal communication will stimulate feelings and attitudes (McCroskey, Richmond & McCroskey, 2006).

Moreover, it seems that nonverbal communication, including kinesics, plays a big part in the overall classroom environment in order to maintain a functional and positive atmosphere (Argyle, 1975). Thus, it is of critical importance for teachers to be mindful of the students' outward nonverbal language as well as of their nonverbal cues. Through observing and interpreting the students' body language and facial expressions, the teacher can discern whether it is necessary to repeat information, provide more assistance, or assign more practice (Webb et al., 1997). In fact, Kontakos and Polemikos (2000) claim that kinesics are less controllable than facial expressions. According to Castañer et al. (2010) nonverbal and verbal communication should be combined in a functional way in order to achieve the efficacy of education and that it has been shown that novice teachers seemed to be more effective than expert ones in this specific procedure.

Though various nonverbal communication taxonomies can be found, researchers (Zoric et al., 2007; Miller, 2005; Knapp & Hall, 1992; Smith, 1979) offer comprehensive and scientific categorization, including chronemics, haptics, vocalics, oculosics, olfactics, physical appearance, proxemics, silence, symbolism and kinesics. It is important to note that each category of nonverbal communication does not occur individually. Rather, they occur simultaneously and in clusters. For the purpose of the present chapter, the focus will be placed on kinesics. Kinesics refers specifically to the skeletal body movement, including the head, torso, limbs, and excluding gaze and facial expressions (Birdwhistell, 1952). According to Messiou (2006), it is underlined that those children who are marginalized gradually adopt an aggressive or even victimized behavior. Messiou (2006) adds that the path to reintegration of these children into the educational system rests on the ability of teachers to identify through the “hidden voices” of the marginalized children. In addition, according to an enlightening study of psychological and educational interest in the school context, it has been shown that inadequate feedback may often provoke the students' aversion towards the educational process or the students' adoption of aggressive behavior (Motte-Stefanidis et al., 2000).

The term bullying will be utilized to encompass all aspects of behaviors, defined either technically or legally, by intimidation, harassment, stalking, or hazing. This term will specify behaviors that include a variety of actions intended to belittle, demean, injure, or deny the rights of others (Roberts, 2017). Children who bully today use more covert than overt means than in the past. They are more likely to be seen engaging in nonverbal violent communication. Bullying commences during elementary school and typically peaks in middle school (Unnever & Cornell, 2003), but evidence demonstrates that predictors of bullying emerge during preschool, between the ages of 3-5 years, which is the first formal context for consistent, systematic peer interaction (Vlachou et al., 2011). Bullying refers to the intentional repetition of aggressive behavior toward an individual over time (Olweus, 1993).

Gaining deeper understanding about the presence of nonverbal violent behavior, considering the importance of each child's safety in the classroom environment, seems to meet all three of the criteria that presuppose the significance of a research topic. Specifically, Miller and Nicholson (1976) note that the first criterion is the theoretical significance, the second is social importance and the third is personal interest. Therefore, we notice that this research topic

can provide further knowledge about observing nonverbal violent communication and bullying behavior, and that it is also occupying social interest, as it is a matter of enormous fascination nowadays. Furthermore, it is a matter of personal interest for both the researcher and/or the teacher from different perspectives and for different reasons mentioned henceforth.

OBSERVATION IN THE CLASSROOM

Observation is a complex procedure with specific requirements from both the educator and the researcher, especially when it concerns the domain of preschool education. Palaologou (2016) identifies educational observation as a systematic and structured procedure with which early childhood teachers record the children's behaviors and reactions, in order to be able to interpret them with the intention of shaping the assessment of their evolution as well as drawing up a future action plan. From this point of view, we understand that it is the teacher's duty to observe the pupils, especially when the teacher's main purpose is the early anticipation of violent communication and bullying in order to deal with and eliminate these behaviors quickly and effectively. The necessity of observing children is found in various theoretical approaches of preschool education. Stemming from the 19th century, both in Froebel's pedagogy and in the Montessorrian approach, the value of observation always had a structural importance in education. In the 20th century, the Walford education system, the pioneering Reggio Emilia training, and the Swedish education program Educare, all underline the need for observation throughout the pedagogy spectrum.

All the aforementioned are being implemented in Europe. Of course, the Bank Street School, High Scope, and Head Start programs are also taking place in the United States, where they also utilize the benefits of observation. Currently, the same situation is observed in New Zealand, wherein Te Whariki is the main element of education, since in addition to pupils and educational staff, both parents and children are involved. Finally, modern education systems such as experiential education consider observation to be necessary, which is why it is included in the UNESCO guidelines (1994). The above-mentioned approaches seem to be in line with the psychological approaches of education with respect to observation. In particular, psychoanalytic theories, behavioral theories, attachment theory, social learning theory, systemic theory, and cognitive theory, are all applied and evaluated mainly based on observation.

Although observational methods are applied differently in the individual programs, these methods are a basic and structural element in all education systems, both from the educational and psychological points of view, and additionally contribute greatly to the evolution of these approaches to this day.

Since observation is critical and distinct in its nature, one must look at its basic elements. In order to apply a functional and effective observation, one needs to know what one wants to evaluate specifically and focus on that topic. On the other hand, one must choose the tool with which one will make the evaluation. For instance, measuring kinesics for the evaluation of nonverbal violent communication and bullying.

Regarding the observation techniques, the following is mentioned: unstructured observation, semi-structured observation, and structured observation. Unstructured observation can be conducted by the teacher as it does not require much preparation, but is based on the

memory and judgment of the learner himself. Semi-structured observation can also be conducted by the department's educator. Its purpose, meaning what one observes, is distinct but the methodology is free and it is certainly necessary to cross-check data from a wider observation team. Structured observation is usually non-participatory, but the purpose and methodology are specific, and the results of the observation are absolute and objective.

OBSERVATIONAL CODING SYSTEMS

Having selected the appropriate observational technique in any given research question, the next step would be to conduct an appropriate coding system. Observational coding is based on explicit operational definitions of a defined set of behavior codes and follows a fixed coding procedure. Codes and procedures are part of a coding system, which is a standard protocol for describing behavior (Bakeman & Gottman, 1987).

Descriptions based on observational coding provide the benefit of measuring body movements by eliminating unnecessary observer inference. According to Stamatis and Kodakos (2008), there are several coding systems presented regarding the classification in analysis of nonverbal behavior in terms of kinesics, some of those are mentioned hereafter: (a) The instant coding system by Rosenfeld (1965), (b) The kinesics analyzing system (Birdwhistell, 1970), (c) The Facial Action Coding System (FACS) entailing detailed rules for coding unit boundaries and phases (onset, apex, and offset) of facial muscle movement (Ekman & Friesen, 1978), (d) The Body Action and Posture Coding System (BAP) is built on body posture units and body action units (Harrigan, 2005).

Considering the BAP system, a posture unit symbolizes the general alignment of one or a set of articulators (such as the head, trunk, or arms) to a resting configuration, which exhibits periodic changes (known as posture shifts; an individual leaning backward, arms crossed). An action unit is a local excursion of one or a set of articulators (mostly the arms) outside a resting configuration with a very discrete onset, a short duration, and a precise offset where the articulator returns to a resting configuration such as a head shake, pointing, arm gesture (Dael, Mortillaro & Scherer, 2012).

Codes describing postures and actions are categorized in two integrated levels. On the first level, BAP codes describe which body part is actively moving, or anatomical articulation, following well-established kinesiological standards (Neumann, 2002). It enables the coding of articulation of the neck (head), trunk (spine and chest), upper and lower arms (shoulders, elbows, wrists, fingers), and the lower limbs (knees).

Specifically, BAP codes apply solely to spatial movement caused by muscle contraction and not passive displacement of any connected articulator (Dael, Mortillaro & Scherer, 2012). On the second level, BAP codes apply to the form of the movement of the active body part. That is, the direction and orientation in a three-dimensional space by adopting an anatomical and external reference frame (Rosenfeld, 1982).

Actions are described on a functional level that is parallel to the anatomical and form description level. Functional BAP codes include Ekman and Friesen's (1972) three behavioral categories: emblems, illustrators, and manipulators. Emblems are conventionalized actions that have exact meanings, of which symbolic actions are cultural-specific and can be used regardless of speech. Manipulators are actions wherein one part of the body manipulates another body

part, or another object for some type of body contact, such as scratching or rubbing. Illustrators are conversational actions that support accompanying speech. They illustrate the rhythm or content of verbalized information. Contrary to emblems, they are associated with speech and have no fixed meaning.

There has been evidence of four methodological benefits of the BAP for emotion research, which could also result from bullying or a nonverbal violent communication situation. The first methodological benefit entails that the BAP coding system has a reliable observation protocol which limits the probability of observer inference in describing emotional expressions and facilitates replication and comparison of results across studies. The second methodological benefit involves action and posture descriptions resulting from the BAP coding system which are independent of other modalities, and particularly speech. The third methodological benefit focuses on the behaviors that can be studied using the BAP coding system which range from head to leg movement, including postures, gestures and other observable body actions. Subsequently, the fourth, underlining that the BAP coding system provides reliable data on occurrences, frequencies, and temporal properties of BAP like timing and duration. All in all, the BAP coding system is designed for, but not limited to, the study of multiple emotions (Dael, Mortillaro & Scherer, 2012).

DISCUSSION/OBSERVATIONAL DESIGN

Therefore, for the purposes of this chapter, the appropriate process of observation first requires the clarification of the operational definitions of ‘violent communication’ and ‘bullying’, which are both variables that are going to be measured. To do so, authors will utilize the information provided about kinesics, from which data is collected via the coding and decoding kinesics’ tools. The technique one follows may either be semi-structured or structured observation. More specifically, the authors should define who the observer will be. If the observer is a researcher, then the authors will apply the structured observation process, but if the observation is applied by the teachers themselves, then the semi-structured observation is more appropriate. Of course, the authors must not forget that both techniques are equally important, because they can provide important data from different approaches. This is also noted by Palaiologou (2016) who states that observation depends on its context. In particular, she states that observation may be applied as part of a research study or as part of a training act. Moving forward to the coding procedure, the categories that could be considered as forms of nonverbal violent communication and bullying in terms of kinesics may be gestures, including pointing and/or lifting the legs or the arms in a threatening manner, etc.

Stamatis (2015) states that body language signals are able to provide information regarding the emotions that a child is experiencing at the moment. Additionally, if bullying and violent behavior are assumed to cause crying, detachment, disappointment, frustration, anger, and violent responses in general, then one would be able to examine any pre-recorded evidence or measurements, in order to analyze and further understand which form of kinesics caused such behaviors. However, Harrigan (2005) underlines that the drawback which occurs in early coding systems for body movement, are that they are very time-consuming systems, there are very large amounts of data to be learned, there is a display of arbitrary symbols and that isolated coding prohibits measuring behavior as a unit.

Once the coding system has been established, a record must be kept of this data. Beyond the traditional methods of record keeping, video recording may provide a wider range of subcategories of kinesics, derived from existing coding systems, or a scale of the observers own making. It would also be used in order to view either multiple threatening communication attempts happening simultaneously or more covert signs of bullying. As previous studies have shown, video recording provides the advantage of instant and objective capture of behavior that could be stored, analyzed and cross-referenced at any time (Tobin et al., 2009; Stamatis & Kodakos, 2008). For example, the Anvil software (Kipp, 2007) is used as a coding procedure for video rendering and time-locked coding and could provide satisfying data, overcoming these challenges. Anvil executes the coding scheme into an intuitive graphical user interface through which the coder can assign codes to the body movements specifying the beginning and the end of the behaviors (Dael, Mortillaro & Scherer, 2012). Video recording also presents some ethical implications such as the need for an informed consent form, the purpose of record keeping, the use of record keeping, the participants in the process of record keeping, who will have access to the records and the sharing of the observations that should be carefully managed (Palaiologou, 2016). Specifically, in the United States, it is mandatory as a communication researcher to follow the guidelines set by the Office for Human Research Protections in order to ensure research ethics (Keyton, 2015). However, in contrast to other means of observational research, it is obvious that collecting such data via video recordings remains an accurate and proper way of observation (Mukherji & Albon, 2015).

As Vrettos (2003) concluded, early childhood educators are not able to observe, record and analyze sufficient amounts of data at one time, as it is impossible to focus on the behaviors of each individual child. A teacher tends to be more preoccupied with the sum of the classroom, as the collective group of the classroom is more easily observable. From the teacher's perspective, a record could be kept using a simple list of observable actions like nervous hand gestures, sudden or unprovoked movements, threatening leg or arm movements, threatening trunk movements, etc. This task is much easier for a researcher merely observing these behaviors, than it is for the early childhood teacher who must interact with the children. A researcher would focus on these observable behaviors and gather information without being concerned with the consequences of such behaviors to the classroom environment. Whereas, a teacher who would observe such behaviors should take action to stop and prevent them in order to keep the classroom environment safe and functional for the children. Nevertheless, this does not mean that the teachers contribution in observation is obsolete or not important, as the teacher is the only one responsible and able to foresee and prevent nonverbal violent communication and bullying in the classroom.

The observation of violent communication and bullying with early childhood children, in the classroom, is a fundamental matter. Researchers and education professionals should aim at identifying those at risk of becoming bullies so that early intervention programs can be developed to target children who show early signs of such bullying symptoms (Jenkins, Mulvey & Floress, 2017). The proper observational techniques and tools (such as BAP) will be selected by the observer, but the data collected should not be interpreted at this stage. Video recordings would provide sufficient evidence for the observer to analyze and interpret the data collected, which is the next step after recording. Finally, the focus should move to how the observation findings will be shared. The researcher would probably publish those findings that could be extremely useful for all early childhood teachers. The teachers should be trained to accurately

encode and decode elements of the students' nonverbal communication (Muchemwa, 2013), with respect to these findings in order to maintain a non-threatening classroom environment.

Chapter 30

CURRENT THEORETICAL DISCUSSIONS ON CHARACTERISTICS OF CYBERAGGRESSION, SCHOOL MISCOMMUNICATION AND BULLYING IN EARLY EDUCATION

ABSTRACT

Traditional bullying has long been a concern for children, teenagers or others who fit the characteristics often tied to targeted victims. Cyberbullying, a relatively new and ever-changing online phenomena, may pose a larger threat in the health and safety of children as it is still being explored with new theoretical lenses and preventative programs and approaches. This chapter discusses a number of concerns surrounding bullying phenomena, suggests a number of theoretical perspectives that researchers should consider when trying to understand cyberaggression among young children. Current research among children with special needs is also reviewed with closing remarks on concerns of miscommunication among school staff, teachers, and parents.

Keywords: bullying, cyberbullying, theory, special education

CHARACTERISTICS AND CONCERNS OF BULLYING

Traditional (face-to-face) bullying has long been a concern for decades as caregivers would send their children off to school into unparented arenas (e.g., the playground) wherein verbal or physical attacks could be directed at their child(ren) at any given moment. One unique factor in the traditional sense is that children could generally consider home a safe space in which

*Corresponding Author's Email: Timothy.Oblad@tamuk.edu.

bullies were not present. Comparatively, cyberaggressive messages could potentially enter any room of the home at any time on any device directed at a child, teen, or adult who connects online on any platform. We know from Olweus (1999) and other researchers (Hainewald, 2013; Beckman, Hagquist & Hellstrom, 2012; Gradiner, Strohmeier & Speil, 2009) that bullies and victims alike often suffer from several psychosocial and psychological problems in both traditional bullying and cyberbullying behaviors. Modecki and colleagues (2014) provided an extensive meta-analysis review of both types of bullying involvement and found that traditional bullying is still quite prevalent (about twice as common as cyberbullying). The researchers also discovered high comorbidity rates in that many individuals are involved in both forms of bullying and can be bullies and victims simultaneously! Other individual studies (Oblad & Trejos-Castillo, 2017) have also found support for this. Perhaps it should not be surprising that an individual who may be small in stature could become prey in the face of a power imbalance but electronically, could hide any distinguishing features, mask themselves with anonymity and retaliate and take revenge on their would-be school bully (König, Gollwitzer & Steffgen, 2010; Wolak, Mitchell & Finkelhor, 2007).

Over the last 10 years, researchers have tried to study the new phenomena of bullying, growing social media, all coupled with the ever-still present risk of traditional bullying. Extensive research indicates involvement typically peaks around 12-15 years of age (Wade & Beran, 2011; Calvete et al., 2010). But studies do indicate that involvement in all forms of bullying may happen from early childhood to late adulthood. Perhaps due to the nature of the adolescent age most bully research tends to focus at this stage in life. In any case, there is a need to review empirical studies that address cyberaggressive behaviors among young children as well as special populations such as children with special needs.

There are at least a handful of valuable studies that focus on early learning ages and are vital to providing an important range of understanding for educators and parents. Jansen and colleagues (2011) for example, conducted a longitudinal investigation that followed preschoolers until ages 11 and 13. Children with anxiety during preschool were less likely to become bullies or victims. Whereas children with preschool aggressiveness, more likely to bully, be a victim or even both! The researchers also discovered children with two parent families were likely to be uninvolved in bullying activities all together. Perhaps this leads to more questions than answers but from this study we recognize the importance of marking early education behaviors and how family situations can help predict bullying involvement at later ages.

In Australia, one comprehensive study provided by Price and Dalgleish (2010) investigated the impact of cyberbullying on pre-teen and teen youth (N = 548) across a myriad of important factors (e.g., well-being, familial/peer relationships). In terms of preliminary results, their initial look at prevalent results indicated that as pre-teens, just under half had been cyber victims (49%) with a slight increase with 13-14 year olds (52%) and among 15-16 year olds, only 29% reported being victims of cyberbullying. Most cyberbullying incidents were self-reported as happening through email, online chatrooms, social networking sites and mobile phones. The researchers also reported that among 10-12 year olds, the majority of online attacks were through chatrooms (48%) or email (41%). Name-calling and abusive comments were the highest reported means of cyberbullying for all age groups.

For children in early education, this information alone can be helpful in protecting children from unwarranted online aggression that many preteens, tweens, or teenagers are faced with. This influential age is very important for normative and healthy development. Given the high

likelihood of interfacing with strangers online or via social media platforms, parents and teachers alike should be thoughtful and strategic in helping children avoid social network platforms or chatrooms that are not age-appropriate, to help them be ready and understand that such unwanted/unwarranted behaviors may happen and most importantly, know what to do when faced with abusive comments or solicitations.

Price and Dalglish (2010) also sought to reveal coping methods to provide insight into how serious the emotional impact of cyberbullying may be. Unsurprisingly, self-confidence, self-esteem were most heavily impacted following loss of friendships. Over one-third (35%) lost focus in school as their grades began to decline as well as regular attendance. 19% felt a strain with family relationships. The authors also found an extensive variety of emotions were felt (e.g., sadness, anger, jealous, annoyed). While feelings are a form of coping, some feelings may lead to maladaptive behaviors (e.g., severe depression, suicidal ideation and self-harm) and is thus important to address early on. With primary school-aged children in mind, the authors shared strategies most commonly used by 10-16 year olds in the study: speak out and address it; ignoring; avoiding; remain positive; and retaliation. These were the most common responses but the most effective (in terms of helpfulness) method was telling a friend or parent. Other strategies included staying offline, confronting the bully, calling a helpline, etc.

Parents and educators should be aware of the risks of online bullying via means of gaming, visiting websites/chatrooms, or having/using social media accounts. Cyberbullying may happen on campus or off-campus, and if care providers are aware of research results such as those that have been discussed above, children and teenagers will already have the tools and knowledge necessary to avoid the negative impact, negative coping methods, and negative outcomes that all-too-often permanently hurt entire families and communities across the world.

THEORETICAL FRAMEWORKS AND APPLICATION

Theoretical frameworks are important to help researchers and policy makers better understand cyberbully (and bullying) phenomena by providing special lenses to the discussion that we may otherwise overlook without a framework or model to help consider new perspectives. Researchers have noted the atheoretical nature of most cyberaggressive empirical work (Oblad & Trejos-Castillo, 2013; Dooley, Pyzalski & Cross, 2009), although some theoretical frameworks have been applied, it is largely to an older audience, often emerging adults or high school students. The following theoretical lenses are examples of frameworks that could help educators, researchers, and parents truly understand why young bullies and/or victims behave the way they do leading up to aggressive attacks as well (and arguably more importantly) as to understand why bullies/victims react the way they sometimes do afterwards.

Social-Ecological Systems Perspective

Harcourt and colleagues (2014) explored parenting experiences relevant to bullying through a systems-level approach. Under the social-ecological systems perspective, bullying is viewed as a complex and social phenomenon, heavily influenced by peers, relatives, teachers and the community (Espelage & Swearer, 2004). Through this lens, bullying activities may be

exacerbated by a surrounding influence of approval and permissiveness or be inhibited by concerned parents, peers or individuals fearing punishment.

Besides externalized conditions (e.g., peer acceptance; parental awareness), individual experience also plays an important factor under this theoretical approach. Individuals that act as bullies may have past experiences that lead to maladaptive behaviors such as turning to bullying to get a desired outcome. Bullies also recognize opportunities in their environment in which there are low risks for punishment. Lastly, individuals may have also witnessed peers interact as bullies and/or victims and depending on the outcome of the witnessed experience, may decide to model that behavior in the future.

As previously mentioned, Harcourt et al., (2014) reviewed studies (N = 13) to explore parental awareness and involvement in bullying experiences. The authors found six themes emerged that support the social-ecological systems perspective (e.g., victim blaming, range of definition, awareness), one surprising theme was the idea of where to place responsibility. The authors suggest that for social-ecological systems perspective to provide an effective lens we must consider the interactions between external and internal factors rather than just one or the other when trying to understand bullying. How parents, school administrators, teachers and student-children interact with one another should work together when dealing with bullying.

Deindividuated Theory

Deindividuation Theory originates several decades prior that describes how crowd mentality forms based on the premise that individual responsibility disappears in favor of large-group norms (Festinger, 1952). Mann and colleagues (1982) explained individuals are more easily able to “hide” in groups and that the theoretical mask of anonymity, is what provides a barrier from any threat of fear of punishment for acting along with a group. Other components have also been added to the theory such as disinhibition (Diener, 1980), the act of an individual falling into a disinhibited state and who then targets a potential victim without restraint or remorse. Today, researchers have applied this to cyberbullying given the nature of indirect, anonymous contact one may potentially have with others.

In 2012, Slonje and colleagues assessed how remorseful cyberbullies felt compared to traditional face-to-face traditional bullies. Their findings were supportive of deindividuation theory as cyberbullies reported lower rates of feeling guilt from attacking others online. One side effect or potential benefit (from perspective of the harasser) is that you cannot see (generally) the targets’ response and that could potentially cause the harasser to send even more cruel content as a means to ensure eliciting harm. Comparatively, traditional bullies do receive an immediate response (e.g., crying, fighting back).

A question that remains unanswered today under this theoretical lens is how children act/react when allowed to spend time online, unmonitored, for large amounts of time. Do young children also fall into deindividuated states and act without remorse as teenagers or college students who have been reported to do (Brandtzaeg et al., 2009)? If so, what can preventative measures can be taken during early childhood education? Another question that should be addressed is what traits or abilities are children capable of displaying at younger ages (e.g., empathy, awareness) to prevent themselves from falling into disinhibited behaviors and attacking strangers online or reacting negatively during online gaming or chatting.

Intergroup Emotion Theory

Theoretical approaches often consider environmental influences but the IET perspective may be helpful to researchers in providing a more salient view in what individuals experience emotionally at a peer- or group-level. For example if a close group of friends encounter one group-member being cyberbullied, at what level of intensity would an individual respond with after being triggered by the aggressive behavior against a peer? Jones, Manstead and Livingstone (2011) investigated this with 10-11 year old students in the United Kingdom. Jones and colleagues discovered that through this theoretical lens peer support played a role in avoiding bullying behaviors as well as allowing bullying (as the aggressor) to happen and simply act as a bystander allowing their peer-group to target someone else and not stopping it.

Social Identity Theory

One theory that may serve as a valuable lens to better understanding young children (as well as all other ages), is through the social identity theory (Amaral & Monteiro, 2002) that suggests identity is directly connected with specific group ties or membership. If an individual, wishes to remain tied or linked with the in-group, he/she may have an expectation from other members to take part in similar activities as to sort of “fit in” or remain united and share a commonality with others. Through this perspective researchers can observe how the individual and the peer group assess how out-groups—or other peers that either do not fit with the group or are just not part of it—are viewed or treated and if a sort of alternative view is developed. Simultaneously, a group may mistreat others negatively but view themselves as better or of a higher status. For example, it could be decided that a targeted individual is ugly and disliked and individuals within a group accept that reality and believe it and praise their own, when in actuality, the targeted victim is lovely and of good report (Brenick & Halgunseth, 2017).

Social Development Model

Catalano and Hawkins (1996) created an expansive model combining elements of other sociological theories with aims to account for determinants in inhibiting antisocial behavior within children (originally geared towards delinquency and substance use). Their model emphasizes the importance of positive connections or relationships with their parents, teachers or other influential characters as providing a protective buffer to antisocial behaviors. In terms of bullying, this particular lens considers attachment/commitment, system values (e.g., school, community), social constraints (e.g., acceptable behaviors) and skills (e.g., cues, problem solving) which are important features often included in anti-bullying educational programs and may be helpful in specifying areas of weakness or concern in which parents, counselors, or teachers can address on an individual-needs basis.

Jenson and Dieterich (2007) conducted a large study across 28 public elementary schools in order to test the social development model as part of a bullying prevention program (also included preventing other type's anti-social aggressive behaviors). Among the randomized sample of fourth graders who received prevention curriculum (N = 670), results indicated that interventions of the anti-bullying program did not change for self-reported bullies. However,

bully-victim scores steadily declined over two years and rates were lower in comparison to the control group ($N = 456$) that did not receive instruction. The program specifically aimed at improving social and emotional skills of children-which fits well as a key part of the core of the originators' model. Nevertheless, overall the authors did not see a markedly positive impact in the reduction of bullying behaviors, but noted that the drop in victimization could easily be tied to an important element in the social development model, that school climate could have been helpful in improving confidence and skills in deterring bullying behaviors. Indeed classrooms were provided training on coping and recognizing social/emotional emotions, which may have influenced follow-up surveys regarding victimization incidents.

General Strain Theory

Perhaps one of the best-known theories in the field, general strain theory has been applied in all types of bullying research due to the main premise of the theory that explains that as individuals are pushed to varying degrees of strain (e.g., anger, frustration), there becomes an increased likelihood to engage or turn towards deviant behaviors (Hay & Meldrum, 2010; Agnew, 2000). Jang, Song, and Kim (2014) applied GST in South Korea involving traditional victims and cyberbullying behaviors (as the aggressor). The researchers' longitudinal study ($N = 3,449$) of 8th graders was able to support the theory as traditional victimization significantly predicted engaging in cyberbullying behaviors. Moreover, that the negative emotions experienced from face-to-face bullying produced enough strain to drive youth towards seeking revengeful behaviors. These findings also support Hay and Meldrum (2010) who conducted an adolescent study in a rural area within the United States. The researchers found self-control and an authoritative parenting style could reduce the negative impact of bullying which are important to know, especially for pre-adolescent ages. The authors also found that victims who did experience negative emotions were at greater risk of deliberate self-harm as peers' abusive behaviors led victims to "self-directed aggression" (p. 554).

Routine-Activities Victimization Theory

Cohen and Felson (1979) first introduced routine-activities four decades prior as a technique to provide explanation for victimization occurring due to unique differences in personal lifestyle or individual choices. Cohen and Felson explained that accessibility (e.g., routine events such as school; or frequent walking routes), suitability (someone who could be targeted), and a motivated aggressor or offender all coming together could lead to criminal or deviant behaviors in such conditions. Particularly, if parents or teachers are not around to prevent negative behaviors or actions. This theoretical lens is unique as it does not focus on roles or observed behaviors but rather it identifies patterns, changes, or conditions in which behaviors such as bullying may take place. Because of the development of cyberbullying and other forms of online harassment, some researchers have recently applied this theoretical lens today.

Wick and colleagues (2017) sought to identify patterns within online harassment among college students whilst applying routine-activities theory. Nearly 300 students completed an open-ended survey sharing experiences of online victimization as well as perpetration romantic

partners. They were able to find some support for the theory by means of exposure to online victimization (more time online predicted more rates of victimization). The same was true for perpetrators, spending more time online predicted an increased risk of acting as an aggressor.

Although Wick et al., (2017) focused on college students ($m = 20.8$) this particular theory could be beneficial for preschool and elementary aged children as it focuses on behavior and environment (situations) rather than individual differences. Most studies that assess bullying and cyberbullying tend to focus on psychopathology, emotionality, familial situations, and a myriad other influential, external or internal factors. As children develop, they change and grow over time, and perhaps those unique factors weigh more heavily with each passing year. However, this theory applied at younger ages could also provide new insight leading to preventative measures that teaches young children to avoid falling into the unique situations that leads to increased risks of bullying victimization (or perpetration) and also help parents or teachers to keep closer tabs on the environment or situations in which bullying risks could be higher.

Theory of Planned Behavior

The theory of planned behavior may be useful to apply when trying to account for the intentions of children's' behavior. Runions (2013) reviewed this particular theory alongside typologies of aggression with a goal to provide a conceptualized model to help researchers and caregivers create effective means of reducing cyberaggressive behaviors. If children perceive bullying (in any form) as normative, they are more likely to take part in the behavior when opportunities arise. The model that Runions creates stems from the planned behavior theory to show why or how aggression may arise, when or how technologies may be creating new opportunities to act aggressively, and why some individuals choose to seize the opportunity or avoid the behavior.

Grounded Theory Approach

Although grounded theory is technically a general method within qualitative research, the inductive approach is applicable in assessing bullying, bullying prevention methods and finding what motivates harassers or even victims. By reducing data down into content-rich conclusions, new theory can be developed and shared with various stakeholders invested in children's' safety and happiness. Recently, a few studies (Greef & Van den Berg, 2015; Purcell, 2012) have used grounded theory as their general method to help shed light on how parents perceive concerns of bullying. Purcell (2012) for example, found through semi-structured interviews that primary school-aged children take part in a series of complex interactions at school and at home and ultimately parents and teachers have variability in their own abilities to accurately and comprehensively address bully behavior. Through qualitative analyses, the author recommended sensitivity and attentiveness towards children and for care providers to be consistent in addressing the impact and events around bullying.

In South Africa, Greef and Van den Berg (2015) also used grounded theory as a method to determine what characteristics emerge among families with children who self-reported as victims of bullying. While the authors did not necessarily apply the framework in their study,

they provided needed discussion on the possibility of resilience theory as a useful theoretical approach to understand bullying through a “complete wellness” (p. 505) perspective at the familial-level. Through this lens, families may handle crises with great success. As the authors discovered, parents often communicated concerns to school officials and authors were able to assess importance of open communication to their child and family.

BULLYING AMONG SPECIAL NEEDS IN EARLY EDUCATION

So far, the present chapter has discussed the nature of bullying and theoretical frameworks to help researchers and policy makers come to a better understanding of the changing phenomena of bullying in reality and electronically. In the wake of a crisis regarding harassment involving powerful people in America, an opportunity for a national discussion on harassment and bullying should include further examination, which includes special or unique populations in which tolerance, prevalence, and severity of harassment and bullying within society. At present, little research has been conducted on bullying within special populations of schools which often include individuals with intellectual disabilities, developmental disabilities, and neurological disorders (Hong, Neely & Lund, 2015; Zablotsky, Bradshaw, Anderson & Law, 2014). Due to the pervasiveness of bullying and the vulnerability of individuals within special needs populations, attention to risk factors for bullying and victimization as well as preventative strategies are vital in moving forward.

Risk Factors of Bullying in Special Education

Special education classrooms comprise a population of students at an exceptionally elevated risk of experiencing bullying. One reason for this may include visible characteristics of disability such as physical disabilities or behavioral disorders, which differ from the larger student population within the school (Swearer et al., 2012; Carter & Spencer, 2006). Diagnosis, severity of disability, and co-morbidity also feed into risk factors of increased bullying and victimization. According to Zablotsky et al., (2013) individuals with ASD have a higher risk of victimization and individuals with attention-deficit hyperactivity disorder (ADHD), conduct disorder (CD), and/or opposition defiant disorder (ODD) are at a higher risk of being a bully and a victim (bully-victim) as compared to their general education counterparts. Gender may also be an important factor to consider when assessing bullying in education as researchers Simpson, Rose, and Ellis (2016) report that females tend to experience higher rates of victimization of bullying and males are more likely to be bully-victims. Age of the student may also be considered as trends in bullying become apparent. Researchers Fink, Olthof, Goossens, van der Meijden and Begeer (2017) report that bullying tends to decrease with increasing age. Moreover, researcher Little found that bullying first peaks at six years of age and then again every 3 years following until 15 years old (Little, 2009). However, of all disabilities, Autism Spectrum Disorders are among those who experience the most bullying (Hebron & Humphrey, 2014).

Prevalence of Bullying in Students with Autism

Autism Spectrum Disorder (ASD) is a neurological disorder, which is comprised of core deficits in communication and social skills and often presents with behavioral impairments. Often, individuals with ASD demonstrate eccentric behavior such as motor and vocal stereotypy as well as inflexible and rigid behavior. Along with these deficits, individuals with ASD often face challenges in forming friendships with their peers and as a result, experience reduced interpersonal relationships. Further complicating matters for individuals with ASD is research showing individuals with ASD are at an increased risk in bullying by their neuro-typical peers (Hong et al., 2015). According to researchers Hebron and Humphrey (2014), interpersonal relationships assist in providing students protection from bullying. As such, combination of behavioral challenges and skills deficits in ASD coupled with limited self-advocating skills further increase the risk of experiencing bullying individuals with ASD face. Moreover, it is reasonable to suggest that bullying remains underreported in special populations where social and communication deficits exist.

Effects of Bullying

Additional factors to consider within a conversation of bullying occurring in schools and in special education settings are the effects bullying has on students with special needs. Current research highlights pervasive symptoms of bullying which may last into adulthood. This includes anxiety, depression, overall poor learning outcomes (Zablotsky et al., 2013; Gladstone, Parker & Malhi, 2006) and various somatic symptoms such as pain and headaches (Williams et al., 1996). Researchers Papas and Axe (2015) report an increased risk of suicide among students with disabilities who experience bullying. Due to the pervasiveness and permanence of the side effects of bullying, effective anti-bullying interventions are necessary part of decreasing the occurrence.

Current Methods of Combating Bullying

In response to a rise in bullying, states are passing anti-bullying laws and there is an increase in the number of schools and universities that are adopting policies against bullying (Gentry, Pickel & Johnson, 2015). Researchers Hebron and Humphrey show that positive relationships protect those with special needs and reduce the frequency of bullying (2014). As such, improving relationships between students with ASD and their neuro-typical peers may assist in decreasing the occurrence of bullying. However, further research on the methods and efficacy of improving social skills among students with ASD as well as improving tolerance of differences among students is needed. One method that shows potential consists of incorporating instructional methods such as video modeling and role-playing as strategies for reducing victimization within special needs groups and providing sufficient opportunities to practice potential bullying scenarios as suggested by Hong and colleagues (Hong, Neely & Lund, 2015).

Due to the trends in age and gender, support against bullying involving students in elementary and junior high school settings may also provide effective settings in which anti-

bullying and victim-advocacy interventions can be applied and tapered. Collaboration across parents, educators may also improve the status quo of bullying within our school systems (Hong et al., 2015). Collaboration among fields increase the possibility of targeting core deficit skill areas including executive functioning, social skills, and communication skills and thus the possibility of improving overall functioning and reducing odd mannerisms or isolating characteristics of Autism. Attending Special education classrooms as opposed to mainstream classrooms via an inclusive teaching model also reduces the frequency of bullying, likely given to the fact that there are less perceived behavioral and social differences among students (Sterzing et al., 2012). Although this platform is not an argument in favor for or against an inclusive teaching model in itself, a higher frequency of bullying within mainstream classrooms compared to special education classrooms was reported by Zablotzky et al., and is a noteworthy factor for educators and parents when determining placement of their students with disabilities.

BULLYING AND SCHOOL AWARENESS

The wise African proverb: “It takes a village to raise a child” is as applicable today-if not more so-than as the time it was first coined. Children and adults alike must navigate an ever-increasing complicated life with changing climates, cultures, platforms for online-engagement and other social and economic forces constantly shifting. Today, children can truly benefit with supporters helping them along from micro-to-macro levels (e.g., caregivers, siblings, teachers, peers, community leaders). Unfortunately, there are instances in which ambiguity hinders the protection of children that could put them at risk for victimization or fall into aggressor behaviors online or in person.

Mitchell (2017) reviewed a well-known anti-bullying program and stressed that to be successful; the entire school-community would need to be well-trained and prepared to handle bullying situations. If para-professionals or other school staff were not trained along with teachers or administration there is a risk bullying could continue despite program flyers, lessons, and class discussion at the school. Such miscommunication would increase risks of mishandling bullying situations that would lead to inconsistent responses, lose opportunity to teach children and potentially have incidents go unreported. Further, parents should be well apprised of any anti-bullying program given as they are an important part of that village! Mitchell added that to be successful, children should also learn early on, how to recognize signs of bullying and be given the tools to stop it by telling a trusted adult.

Research over the last 10 years has explored the role teachers, caregivers and peers play to help us understand both the harasser and the targets state of reference. To date, most research indicates that traditional bullying is made aware to teachers or parents by the target but the same is not true for cybervictims. In 2008, a study by Smith et al., (2008) in the UK found that secondary school-aged children who had reported themselves as cybervictims also reported not telling anyone about the incident(s) (44%). Among those who had shared their victimization experience, just over a quarter of victims (27%) told their friends, and only 15.5% of the victims told a parent/guardian. Teachers or other adults were tied just over 8%. As discussed prior, the authors also found that traditional victims were more likely to share or report the experience than those comprised of targeting online-only.

Nearly 10 years after the aforementioned study, Sittichai and Smith (2018) found strikingly similar reports albeit in Thailand! Among the cybervictim-group, only 29% of children reported that they would seek help from a teacher or parent. They also found nearly half of the victim group (48.4%) tries to ignore it. Interestingly, the researchers also found girls were more likely to seek help, tell an adult or teacher than boys were. This information is important globally to help us understand that many victims of online targeted aggression try to handle it by themselves and prefer to talk to peers about it rather than seeking adult help in any form. Sittichai and Smith provide a great discussion on the concepts of gender, age differences, and trust issues with teachers and parents and most importantly, that consistent collaboration is of most importance in order to help foster children and allow them to identify positive coping methods and find a way to strive through difficult experiences, especially early on.

Chapter 31

PRESCHOOL TEACHERS' PERCEPTIONS ABOUT THE EFFECTIVE INTERVENTION FOR BULLYING AT THE PRESCHOOL AGE

Eleni N. Nikolaou^{1,*} and Georgios M. Markogiannakis²

¹Department of Sciences of Preschool Education
and Educational Design, University of the Aegean, Rhodes, Greece

²Independent Researcher, M. Ed., Rhodes, Greece

ABSTRACT

The aim of the present research is to explore preschool teachers' perceptions about the effective intervention strategies. Teachers' perceptions are important as they affect their attitudes and responses to bullying incidents. Furthermore, teachers are key agents of intervention efforts. The sample of the present research consisted of 164 preschool teachers. A questionnaire was administered based on previous research. The results indicated that the collaboration between school and family as well as the discussion with children about bullying behaviors are considered the most effective strategies for bullying intervention at the preschool age. Moreover, supervision of school areas and cooperation with community services are highly valued. The findings could be utilized in the design and implementation of interventions for addressing bullying. They also have implications for in-service training and ongoing professional development.

Keywords: school bullying, preschool teachers, perceptions, interventions

INTRODUCTION

School bullying is a widespread phenomenon which constitutes a serious social problem internationally. Many studies have been conducted regarding school bullying in elementary years and adolescence, whereas research studies at the preschool age are limited. Bullying can

* Corresponding Author's Email: enikolaou@rhodes.aegean.gr.

take many forms, direct and indirect. Direct bullying is directed towards a child which is the target, whereas indirect bullying refers to the social isolation and exclusion of a child from the peer group (Trigka-Merigka, 2015). Olweus defines bullying as a repeated aggressive action which has the intention of harming (physical or psychological harm). Simultaneously, there is an imbalance in the relationship between the perpetrator and the victim (Olweus, 1993). The present study aims to explore preschool teachers' perceptions about the effective strategies for addressing bullying incidents. Teachers are key agents in implementing anti-bullying interventions and therefore their perceptions are crucial to the effectiveness of the efforts for addressing bullying. In addition, their perceptions affect their responses and should be taken into account in the design of anti-bullying interventions.

ETIOLOGICAL FACTORS

The biopsychosocial approach or the theory of ecological systems was proposed by Bronfenbrenner (1979). According to this approach, five systems influence the development of children: the microsystem, the mesosystem, the exosystem, the macro system and the chronosystem. Biological agents also contribute to these systems. Both environmental and biological factors shape the development of the child.

The environment consists of a set of interrelated embedded structures. The microsystem is a set of activities, social roles and interpersonal relationships that the developing person is experiencing in a particular context. It is the immediate system in which the child belongs. Examples of microsystems are the family, the school and the peer group. The mesosystem refers to the relationship between two or more contexts. For example, the relationship between family and school, as well as the relationship between school and workplace.

The exosystem has an indirect impact on the development of children through its influence on the family, school and peer group. It includes the relationship between two contexts, of which one does not include the child. However, the events taking place in this system exert an indirect effect on the context in which the child is embedded. The workplace, family social networking, the neighborhood context, and the community exert an indirect influence on the development of children. The macro system includes social norms, lifestyle, cultural values, the economic conditions, culture, ideology, politics and legislation. According to Swearer and Napolitano (2011), individual risk factors are the following: gender, ethnicity, socioeconomic status, poor social skills, low academic achievement, and disability status, externalizing behaviour and internalizing disorders. Peer group risk factors include peer norms and delinquency. Family characteristics, such as family discord, are related to bullying. School risk factors include the school climate classroom characteristics and teacher attitudes. Neighborhood safety is a community risk factor.

LITERATURE REVIEW

Perren and Alsaker (2006) argue that preschool teachers refer to aggressive actions directed at harming the relationship, although physical and verbal aggression is more common in this age. Indirect victimization, according to the educators, was the strongest predictor of physical

and psychological symptoms of stress in children. Consequently, indirect victimization is a significant aggressive action that also manifests at the preschool age. Yoon and Kerber (2003) suggest that teachers should discuss with students about bullying instances, class and school rules. Social skills training is also included in the intervention strategies. They also assert that teachers need a better understanding of social exclusion.

Roberts' (2011) study indicated that teachers evaluated the interventions implemented by the non-teaching staff for addressing all forms of bullying as most effective. These interventions include counseling support groups for victims, peer mediation programs, as well as training for teachers and school staff. They also asserted that the interventions implemented by teachers are more effective than those implemented by students. Gorsek and Cunningham (2014) assert that it is essential that teachers and school personnel be trained to recognize all types of bullying and become aware of school policy regarding bullying prevention and intervention, which should be integrated into curriculum. Moreover, professional development opportunities could support teachers in implementing prevention and intervention.

Repo (2015) points out that the phenomenon of school bullying is a daily phenomenon. Intimidation is perceived as a desire or need of a child to intentionally offend or harm another child. According to the kindergarten teachers, the child which intends to harm others is aware of his actions. Some children dominate over the others and manipulate the group, using invitations to birthday parties. The list of invited children at the party changes depending on whether the children act as expected by the perpetrator of intimidation. This research showed that preschool children were aware of the phenomenon of victimization and were able to describe it. In addition, the exclusion from the peer group was categorized by children as bullying. The characteristics of victimization in preschool environments were already evident. According to Repo (2015), the intervention strategies for bullying include the protection of victims, assertiveness training, broader interventions in the classroom (discussion of bullying in the kindergarten group), clear rules against bullying, involvement of peers and the promotion of friendships. Withdrawn children should also be encouraged to participate in group activities.

Stamatis and Nikolaou (2015) research study explored teachers' views on communication and collaboration between school and family for effectively addressing school violence. The survey was conducted in 2015. The sample of the research was one hundred and thirty primary school teachers, who were teaching in public schools in the city of Rhodes). The analysis of research data suggests that teachers regard the collaboration between school and family for combating school violence as important. In addition, they believe that this cooperation is of particular importance as it could: (a) enhance children's positive attitudes towards school and improve their behavior within the school environment, (b) improve their social skills, which contribute constructively to their socio-emotional development (c) strengthen children's relationship with his/her parents and teachers and, in the long term, enhance his or her bonds with the school.

Morin (2017) conducted a review regarding the interventions for countering bullying. The interventions were classified into three categories. The first category was the intervention on individual level. Literature suggests that when teachers encourage positive behaviour, positive social interactions, and asking help from a friend contribute to bullying reduction. Positive self-talk, I-messages, peace journals in pictures, changes in the preschool environment and the promotion of children's social skills are also included in the interventions on individual level. Interventions on group level constitute the second category. Training children in pro-social strategies is an intervention on group level. It is suggested that teachers should role model pro-

social strategies, be aware of the social dynamics and relationships within the child group, identify children at risk, and reinforce positive behaviour in the group. Literature highlights the importance of a positive relationship between teacher and students and the use of activities that cultivate cooperation. The third category refers to the interventions targeted at the environment. Teachers are expected to inform families of social rules at preschool for promoting the same rules at home. The use of structured play which fosters children's participation, monitoring the room during free play, classroom rules against bullying, and the design of an anti-bullying curriculum are comprised in the interventions targeted at the environment.

A training program that could be used for bullying prevention and intervention is the Incredible Years Dinosaur (Webster-Stratton & Reid, 2004), which aims at enhancing socio-emotional well-being at the preschool age children. It consists of social and problem-solving skills. Simultaneously, it aims at preventing behavioral problems and enhancing academic attainment. The program focuses on the following topics: empathy, emotional literacy skills, interpersonal problem-solving, anger management and communication skills. Training in interpersonal problem-solving can act as a preventive measure. In Greece, the Mental Health Promotion Program "I Can Solve the Problem" (Shure, 2000) was implemented, which a primary prevention program is aiming at strengthening the interpersonal problem-solving skills of preschool children with statistically significant results (Chiou et al., 2005).

Training children in bullying includes the axes: knowledge, attitudes and skills. Teachers can develop the knowledge and understanding of young children by discussing the concept of victimization, the various forms it can take, the harm it can cause, the reasons for which bullying behaviors are unacceptable, and what can be done to address the phenomenon. Attitudes and values can be developed by teaching young children to show empathy to the victims of bullying. The development of a sense of responsibility to help children who are intimidated and acceptance of diversity is also vital to addressing bullying. The skills that are important to be acquired are linked to the ability to protect victims from perpetrators and the ability to manage negative emotions, such as anger. It is also important for children to acquire conflict resolution skills, to peacefully resolve their differences, to provide help, to discourage children who are intimidating, to accept and support children who are intimidated. It is critical that children learn tolerance to the differences in the preschool age and what it means to accept yourself and others as they are. Awareness of the various forms of victimization is also essential. Recognition of the forms of victimization and intervention can prevent future bullying (Levine & Tamburrino, 2015).

METHOD

The sample comprised of 164 preschool teachers from public preschool settings. Overall, 90.2% of the respondents were female and 9.8% male. 23.2% of the participants were aged between 22 and 30 years, 35.4% of the participants between 31 to 40 years, 32.9% were aged between 41 and 50 years and 8.5% of them were above fifty years. Out of 164 preschool teachers, 44.5% reported teaching from 1 to 10 years, 28.7% had taught 11 to 20 years and 14% of the respondents had more than 21 years of teaching experience. Descriptive statistics of the sample are presented in Table 1.

The survey was based on a review of current research literature regarding teachers' perceptions about bullying at the preschool age. A questionnaire was administered to the participants based on previous research (Psalti, Kassapi & Deligianni-Kouimtzi, 2012). The questionnaire was divided into two sections. The first section included demographic data and the second an array of vignettes with the aim of exploring the definitions of bullying and the frequency of bullying incidents. It also included a series of statements regarding teachers' perceptions about the effective strategies for bullying prevention and intervention, which were assessed with a five-point Likert scale. The data presented in this chapter are part of a wider research.

Table 1. Distribution of frequencies of the demographic data of the sample

Gender	Frequency N = 164	Percent (%)
Male	16	9.8
Female	148	90.2
Age		
22-30	38	23.2
31-40	58	35.4
41-50	54	32.9
>50	14	8.5
Work experience		
1-10	73	44.5
11-20	47	28.7
>21	23	14

RESULTS AND DISCUSSION

Table 2 shows that the majority of the participants in this study (97.5%) regard that the collaboration between school and family is very effective for addressing bullying, 7.3% have a neutral stance and 0.3% regard discussion and collaboration as ineffective.

Table 2. Distribution of participants' responses regarding the most Effective Strategies for children about bullying intervention

Which of the following strategies do you regard as most effective for addressing the behaviors described in the vignette?					
	Not at all Effective %			Most Effective %	
	1	2		4	5
1. Discussion with students for addressing bullying	5		14		80
2. Supervision of all areas at the school	7.30		18.30		73.70
3. Use of sanctions	27.50		23.80		47.60
4. School-Family collaboration	0.30		7.30		97.50
5. Cooperation with colleagues	7.90		12.80		77.50
6. Cooperation with School Counselor	9.70		18.90		70.80
7. Cooperation with community Services	4.30		28		62.20

This finding aligns with previous research (Nikolaou & Markogiannakis, 2017; Stamatis & Nikolaou, 2016). Parent involvement to intervention is of fundamental importance. Ttofi and Farrington's (2011) meta-analysis highlights that parent meetings and training, parent-teacher conferences and information for parents can prevent bullying incidents. Moreover, effective programs include school-family collaboration (Olweus, 2001). An ecological framework highlights the significance of multiple levels of intervention. Family and community connections is vital to be established (Mann et al., 2015).

Discussion with students is regarded as highly effective for addressing bullying by 80% of the respondents. 14% have a neutral stance, whereas 5% regard discussion with students as ineffective. This finding is in line with previous research (Yoon & Kerber, 2003). They explored teachers' attitudes about intervention strategies and proposed the discussion with students about bullying episodes and school rules. Repo (2015) also supports that efforts for combating bullying include broader interventions in the classroom and open discussion in the kindergarten group.

77.5% of the sample considers that the cooperation with colleagues is a very effective strategy. 12.8% has a neutral stance and 7.9% considers the development of empathy ineffective.

Supervision of all areas at school is considered as an effective strategy for intervention regarding school bullying by 73.7% of the respondents. 18.3% of the sample has a neutral stance, and 7.3% consider this strategy a little effective. The relevant literature suggests that improved playground supervision and discussion with students about everyday conflicts and interactions between classmates in the playground are an important part of anti-bullying intervention (Pepler et al., 2004). Farrington and Ttofi (2009) argue that playground supervision is strongly related to program effectiveness. 70.8% of the respondents regard that the cooperation with a school counselor is very effective in intervention efforts. 8.9% has a neutral stance, whereas 9.7% regards this cooperation as ineffective.

The cooperation between school and community services is considered as an effective strategy by 62.2% of the sample. 28% of the participants in this study have a neutral stance, and 4.3% consider this cooperation ineffective. The development of partnerships with community services could provide prevention education at school and support for children displaying severe difficulties, such as counseling or referral to appropriate services (Pepler & Craig, 2014).

Finally, the use of sanctions is regarded as a very effective strategy by the 47.6% of the participants. 23.8% have a neutral stance, whereas 27.5% regard this strategy as ineffective. Overall, this strategy is regarded as the least effective by the preschool teachers of the sample. A sanction for bullying is a part of bullying intervention programs. Milsom and Gallo (2006) argue that the goals of interventions should include increasing teacher awareness of bullying, the development of clear policies that highlight consequences for bullying and constructive disciplinary practices. Disciplinary strategies related to the removal of the student from class and school environment are not considered to be effective (Ayers et al., 2012).

Farrington and Ttofi (2009) assert that parent training meetings, improved playground supervision, disciplinary methods, teacher training, classroom rules are the most important elements of intervention programs. Kolbert, Schultz and Crothers (2014) contend that an intervention at various levels, such as the development of partnership between school, family and community is postulated by the social-ecological framework. School bullying intervention includes interventions that target at the classroom level, such as classroom discussions, as well

as interventions targeted at all school community members, including staff, students, and parents. Literature supports a multilevel approach directed at the entire school context (Hui, Tsang & Law, 2011).

CONCLUSION

All the above strategies are regarded as effective and they are all included in a systemic approach to the intervention regarding school bullying. The findings indicate that teachers regard that the collaboration between school and family, the discussion with students, the cooperation with colleagues, and the supervision of all areas at school are among the most effective strategies. They also value the cooperation with school counselor and community services. The data have practical implications for the design of interventions and training programs. Teachers' perceptions regarding the effective strategies are critical to the effectiveness of the implementation of intervention, as they are among the key agents of intervention.

Veesnstra et al., (2014) contend that teachers' responses to bullying may exacerbate bullying. Students often believe that teachers are not able to protect them. The understanding of the relation between teachers' responses and bullying occurrences could affect the design of effective interventions. Teachers and students should be taught strategies to support the victims and should not underestimate the severity of bullying episodes. In-service training and professional development opportunities may enhance teachers' knowledge of effective practices and their feeling of self-efficacy regarding intervention skills. Simultaneously, they may develop supportive attitudes toward victims. As the collaboration between school and family as well as the discussion with children about bullying behaviors are considered the most effective strategies for bullying intervention at the preschool age, teachers should be important targets of anti-bullying efforts, which require a whole school approach and the participation of all stakeholders.

Chapter 32

TEACHING SOCIAL SKILLS, EMPATHY AND ASSERTIVENESS BY TEACHERS AND PARENTS TO PREVENT EARLY CHILDHOOD VIOLENT COMMUNICATION AND BULLYING: TOWARDS A NONVIOLENT COMMUNICATION EDUCATION

Panagiotis J. Stamatis* and Afrodite V. Ntouka

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

According to the findings of current studies aggression has made its presence extremely known in the form of violent communication and bullying even in younger children. This chapter refers to the role of early childhood teachers and parents who can separately or inclusively help children (directly or indirectly) in their efforts to effectively deal with violent communication and bullying. Effective addressing of aggressive attitudes helps children develop into calm and nonviolent personalities, succeeding in their personal, family, work, professional, social and any other context or state of their lives. Within this framework, a variety of teaching activities is recommended that could be practiced at school with the help of early childhood teachers or at home with the involvement of parents.

Keywords: social skills, teaching activities, parents' involvement, communication, bullying

INTRODUCTION

According to the literature, aggression is an instinctive behavior, which occurs in every living being as an inherent mechanism of survival, self-protection and domination on

* Corresponding Author's Email: stamatis@rhodes.aegean.gr.

individuals of the same or another kind, on familiar or foreign group members etc. (Oren, 2015; Stamatis, 2013). Normally, aggression is controlled by the individuals themselves, who can restrain their aggressive tendencies whenever necessary, disciplining between their personal powers, desires, beliefs, needs, motivations, etc. and the rules that define socially acceptable behaviors in the context of ethics, logic and consciousness (Alvarez & Bachman, 2016). In pathological cases, individuals cannot voluntarily control their aggression. In these cases, medication, counseling or psychological support is required. In extreme cases, dangerous aggressive behavior may be treated with corporal punishment, reformation or imprisonment.

In modern times, social problems continue to grow while public expenditure on social policies has internationally decreased. As a result, there is a steady increase of aggression levels in every social group, even in groups of young children. School bullying is a typical case of aggressive behavior in everyday reality. In school settings, this reality manifests itself in various forms, such as physical, verbal or psychological violence exerted by children-bullies towards children-victims who suffer the consequences of aggressive or passive-aggressive behavior (Adams, 2016; Brandt & Rhoschild, 2013).

The exposure of young children to bullying situations taking place either at school or at home must be addressed promptly and effectively. Therefore, the role of teachers and parents is considered to be extremely important. Teachers and parents can act individually or collaboratively if they wish to achieve better results in effectively addressing bullying at school, at home or in the wider social environment. In this chapter, some classroom activities are discussed for the development of early childhood pupils' social skills, which are considered essential for the prevention of early childhood violence and bullying. The school of 21st century, the school of today and, even more, the school of the future must stand out for providing a highly cognitive, emotional, nonviolent and communicational education. All members of each school community should communicate with calmness, courtesy, mutual respect and logic, applying a commonly accepted framework of communication rules. The reification of such schools may be possible only when early childhood education becomes the central concern of educational policies, because the children of that age are the future of every society.

TEACHING SOCIAL SKILLS IN EARLY CHILDHOOD SCHOOL ENVIRONMENT

Young children need to learn and effectively apply many social skills to prevent and face the possibility of developing violent communication and bullying behaviors. The pre-school environment constitutes a natural learning environment and a safe haven where children can acquire and practice social skills. Early childhood education teachers can teach, educate and prepare young children to practice the appropriate skills to develop friendships and help in curbing and preventing violent communication and school bullying (Kodakos & Stamatis, 2002). Social skills can be taught to children through presentations, discussions, narratives, video games, role plays, puppetry, games and activities related to the curriculum, adapted to the age and developmental level of pre-school children. Young children are particularly keen on acquiring and practicing social skills when concrete examples are provided to them, which they can understand and apply them to their life. Kindergartens have the opportunity on a daily

basis to allow children to do what they have learned and guide them by giving them suggestions, encouragement, and feedback. As children begin to acquire social skills, pre-school teachers can gradually reduce their level of support towards them (Stamatis, 2011). Three of the most important social skills related to the prevention of school bullying are empathy, self-confidence and problem solving. These skills and activities that could be developed in pre-school education in the framework of Communication Education are described below in more detail.

Empathy

Empathetic children react with affection to what others think and feel. They understand that school bullying hurts like violent communication and all violent behaviors as well. They are less likely to intimidate and more likely to help children who are victims of school bullying. Preschool teachers can help pupils understand how children who are bullied feel and how they would feel if they were intimidated. In kindergartens, the implementation and practice of specific activities can protect young children from becoming bullies. Such activities may include what is mentioned below. Preschool teachers may change parts of the proposed activities using their imagination and experience.

Description of Emotions

Preschool teachers ask children to describe how they would feel in the case they saw someone being intimidated or if they were victims of intimidation themselves or if they intimidated another child. Then, teachers explain to the children that violence can lead to strong feelings, such as anger, wrath and fear. While it is acceptable for somebody to feel these emotions, it is never acceptable to react by committing violent actions, such as hurting someone deliberately. Teachers conclude saying that with the cooperation of the whole class, it is possible to fight intimidation, so that no child in their group will ever need to experience the intense feelings that bullying provokes.

Different and Similar

Early childhood teachers talk with the children about the fact that all people, young and old, differ from each other in many ways. Some children are big, and others are small. Some children run fast, and others run slowly. Some kids prefer to play with blocks and others like to paint. Then, educators ask children to think and answer the question, “How would their group be if they were all the same?” If they were all like one another, it might be nice at first, since everyone would agree on everything, but gradually it would become boring as they would never try something new or something different. Differences between children make their team stronger, more interesting and more capable of doing different things. Then, teachers explain to children that “bullies” may intimidate other children simply because they are different, trying to make the differences look like bad things or weaknesses rather than assets as they really are. Then, teachers discuss the many ways in which children look like one another. All children eat, sleep, grow and have feelings. All children are hurt when they are forced to do something they do not want to. At the end of the activity, teachers summarize by explaining that everyone should agree to appreciate individual differences, recognize that nobody likes to be intimidated and that they should never threaten someone simply because he/she is different.

Helping Others Feel Better

Initially, teachers ask children to discuss with their group what they could do to help others feel better and how they could understand the feelings of others. The children might answer that they would ask the other children to express how they feel or they would observe their facial expressions and body language as well as their behavior in general. In this way, somebody could understand if a child is happy or sad, if s/he feels bad, if s/he has friends or feels alone, etc. Then, teachers ask pupils to say what they could do to cheer up a sad child and make him/her feel better. Children, in this case, usually answer that it would be nice to pay attention to what a sad child says, reward him/her and invite him/her to play with them or other children.

Extending the activity, teachers could use role-play to help children practice recognizing a child who is feeling sad and helping this child feel better. They divide the class into pairs and ask one child to pretend that s/he feels bad because s/he has been intimidated, whereas from the other child they ask to play the role of the supporter who tries in various ways to make the child who has been bullied feel better. Then, teachers ask children to change roles and repeat the activity. Finally, the teacher discusses with all the children in the class the experiences they gained after playing each of the two roles in this activity.

Acts of Goodness

Early childhood teachers discuss with the children how a gentle gesture may become the opposite of violence, as it helps the other person feel better. An act of kindness usually creates positive emotions. Then, they ask children to describe a good act they have done, how that act made the other person feel, and how they felt themselves by doing this act. In addition, teachers ask each child to prepare an act of kindness that s/he would perform on that day for another child in the classroom. At the end of the day, teachers talk with the children about the good deeds they have done and the feelings they experienced themselves, but also the children who received these acts. Finally, teachers point out that a good act is not just a wonderful thing to do for someone else, but something that makes you feel nice, as well.

The Golden Rule

At the beginning of the activity, early childhood teachers ask children if they have ever heard the Golden Rule saying, “Do unto others what you would like them to do to you.” The same rule could also be expressed as “Do not do to others what you would not like them to do to you.” Then, teachers ask if the children who intimidate care about the feelings of other children and if they treat others the way they would like others to treat them. Later, they discuss several cases of the things they would not like to suffer from others or do to other children, for example:

- “I would not want anyone to say I’m a fool, so I will not say “You’re stupid” to anyone else.”
- “I would not want someone to pull my hair, so I will not pull the hair of someone else,” etc.
- After this activity, teachers discuss about things that children would like others to do for them and what they might do for other children, for example:
- “I would like someone to ask me to play together, so I will ask someone to play with me.”

- “I would like someone to tell me that I have painted a beautiful picture, so I will tell someone that s/he has painted a wonderful picture.”

The activity is completed after reminding the team to treat other children the same way they would like others to treat them.

Modeling Mutual Assistance

Teachers discuss with the children about the ways in which bullying behavior leads both the child who intimidates and the child who is bullied to disrespect one another and feel more like enemies than friends. Then, teachers could use pictures, stories, puppets, or other aids to give examples of the various ways that children and adults can show they care about the feelings of others and can help each other. Finally, teachers discuss how affectionate behaviors make both the “giver” and the “receiver” feel joyful and lovely. In this way, teachers provide children with affectionate and non-violent models that highlight the important role of solidarity to others.

Self-Confidence

Children who are self-confident can defend themselves and others in a fair and respectful way. They know how to deal with a “bully” in an effective and non-aggressive way, and are less likely to become the first target-choice of “annoyers” (Richmond & McCroskey, 1997). Early childhood teachers can help young children use their abilities to prevent intimidating behaviors and to stand up to potential school bullying by defending themselves and others without using aggressive behavior, but self-confidence. Learning assertiveness skills helps someone express their feelings and defend their rights in a way that respects the feelings and rights of others. Self-confidence skills can help young children (a) achieve their goals without intimidation, (b) avoid becoming victims of intimidation, (c) react effectively when they are intimidated (without counterattacking or submitting), and (d) defend children who are targets of intimidation. Both boys and girls must be taught self-confidence skills as an alternative for accepting aggressive behavior in boys and submissive behavior in girls. The help of intimate adults, such as parents, siblings and teachers, positively contributes to the development of assertiveness skills and the stopping of bullying. In this framework, teachers could carry out the following activities to help young children develop and practice the self-confidence skills they need to succeed in preventing and tackling school bullying.

Stay Calm

Activities for developing self-confidence can begin by teaching simple relaxation and self-restraining techniques to address any negative emotion. At the beginning of the activity, early childhood teachers could discuss with children how people who experience a bullying situation may feel, if they feel angry, afraid, sad, upset, embarrassed, and confused or all these feelings combined. Then, they ask pupils what people do when they feel us such. Are they shouting, hurling objects, breaking things, hiding, crying or trying to make someone else feel the way they feel themselves? Depending on the responses they receive from the children, teachers ask children again if they think that these behaviors are good or useful, explaining that sometimes a person can experience intense negative emotions. These feelings are important because they

often tell us that something is wrong and needs to be corrected. But, strong emotions can also lead people to wrong behaviors, unless they learn how to calm themselves, keep their temper and do the right thing to improve a situation. After that, educators ask children to say what they could do to keep their calmness and coolness whenever they feel angry, frightened or upset in a bullying situation. After listening to the children, teachers suggest the following techniques in order to maintain their calmness in situations of intense stress due to intimidation: (a) closing their eyes, (b) taking many, slow and deep breaths, (c) counting slowly up to ten, (d) feeling proud that they remain calm, (e) relaxing the muscles of their face and body, (f) speaking silently to themselves by repeating the phrase “stay calm and restrain (yourself),” (g) drinking some water, (h) sit next to a person they trust. Finally, teachers ask each child to choose the best techniques and practice them.

Ignorance

Children trying to intimidate other children often seek an occasion, a word or a sign against their provocative behavior. If children learn how to actively ignore behaviors associated with intimidation, the potential “bullies” may lose interest. Teachers explain to children that when another child does minor things that annoy them without hurting them, they can often make the child stop by simply keeping their temper and ignoring him/her in an active way. The ways of active ignorance include stopping the game, moving away from the child that teases, turning the body in another direction, avoiding the gaze, refusing to answer a question, and being indifferent. In the framework of exercises that strengthen the skill of ignorance, teachers, after discussing with children, can play the role of the “bully” and show how the child that is provoking often loses interest, when one or more of his/her efforts have been ignored.

“Yes or No”

Early childhood educators can teach children how to respect their own rights and the rights of others, how to reject an intimidating claim and how to accept a polite request instead. In this activity, children exercise their ability to decide whether to politely answer or not to a question or a request as well as to accept the “no” or “yes” of other children.

At the beginning of the activity, teachers ask children what they would like to say to a child who is persistently asking for a specific toy. If the children respond that they would like to refuse, then the teacher asks them how they should say no. If the children answer that they would like to accept, the teacher should explain the difference between demanding and asking politely for the acquisition of something. They can show this difference by coloring differently their voice or using the word “please.” Then, teachers explain to the children that it is always acceptable for somebody to reject an intimidating request. But, if a child is kindly asking for something, then they can choose whether to accept or refuse to do what this child is asking for. After that, the teacher divides the children into pairs and gives a toy to one of the children. Then, s/he asks the child without the toy to demand the toy that the other child has. At the same time, the educator asks the toy-holder to keep his/her temper and respond dynamically “No, I am now playing with it. You can have it when I'm done.” Then, the teacher tells the child who does not have the toy to politely ask for it. The other child can choose to answer politely either “No, I'm playing with it. You can have it when I'm done” or “Yes, you can play with it now.” Finally, the educator asks the child without the toy to answer by saying “Okay, I'll wait until you're done” or “Okay, thank you for allowing me to play with it.” The same role-play continues with all the pairs.

Intimidation's Tackle

It is important for young children to learn how to react in an active way to school bullying. When they know how to assert their rights and vigorously defend others, they gain a sense of control and self-confidence that they can deter others from engaging in violence. Early childhood teachers can teach children that are being intimidated and children who are witnesses of bullying situations how to stop intimidation by responding confidently to the “bullies” or by asking for help from an adult. Teachers can begin this activity by discussing the best ways to respond to a bullying situation. They ask children to say what they think will happen in case they face a child who intimidates with a counterattack or if they reward his/her behavior by showing subordination. Teachers conclude that if children succumb, intimidation will continue. After that, they explain to the children that the best way to stop a bullying behavior is to react dynamically to intimidation by claiming and defending themselves, whether they are intimidated or whether they see another child experiencing intimidation. Then, teachers remind the children that they can ask for help from an adult, as they are facing a difficult situation. The use of similar activities would allow children to practice tackling intimidation by showing self-confidence instead of indifference and not hesitating in asking for help from an adult person they trust. The successful confrontation of bullying needs zero tolerance from its very beginning.

Problem Solving

Children, who can solve problems, know how to analyze and resolve social problems in a creative way (Xanthakou & Kaila, 2011). School bullying differs from other social problems that children may experience. For example, while a conflict can be resolved through negotiation and compromise, intimidation cannot, because it involves an inequality of forces, as the one who intimidates has more power than the victim. Solving a problem related to school bullying requires an analysis of the problem from the target-victim's and/or attendees' perspective and sometimes the teacher's intervention.

Early childhood teachers can help young children understand the problem of intimidation and how to use a variety of constructive, non-aggressive problem-solving skills to help prevent and tackle school bullying. The development of these skills goes through the stages of clarifying the problem, finding solutions, anticipating possible impacts and choosing the most effective solutions. The following activities give young children the opportunity to develop and practice the problem-solving skills they need to help prevent and counteract the phenomenon of school bullying.

Scenarios and Consequences of Bullying

In this activity, teachers present children with scenarios describing cases of bodily, verbal and social intimidation. Then, educators ask children to think and suggest possible ways of coping with these situations as well as the possible consequences that will arise in every case. By exercising role-play between teachers and pupils, an opportunity is provided for practicing potential bullying scenarios in which adult's help may be needed.

Problem-Solving Team

In this activity, teachers ask children to work together as a problem-solving team to solve a problem - a painful behavior (verbal, physical or social) that, if not stopped, may turn into intimidation. Then, the children are invited to reflect on and discuss the following scenario: "Two children want to play at the same time with the same toy. One of them demands and takes the toy violently, while the other child succumbs." Teachers explain to children that most school bullying behaviors start from similar situations, when a child demands and succeeds in taking what s/he wants by exerting violence on another child who succumbs. Finally, after providing pupils with more related scenarios, teachers ask children to discuss and suggest solutions as an outcome of their working groups.

TEACHING SOCIAL SKILLS IN FAMILY ENVIRONMENT

Parents' co-operation with early childhood teachers on the level of bullying prevention among their young children is extremely significant. Parents can become teachers at home and teach their children in a pleasant and effective way using various methods. Initially, parents should realize that the daily discussion about bullying in a friendly and supportive mood helps children understand its characteristics and dimensions. For example, parents should talk with their children about the meaning of intimidation, share personal stories about intimidation, help their children distinguish between funny teasing and offensive mockery (among other children behaviors that occur inadvertently and deliberately), encourage their children to socialize and not exclude their classmates, read books about intimidation with their children, etc.

In some cases, parents need help from teachers in order to understand how those behaviors of bullying in early childhood are expressed and for what reason an intervention for prevention is important. Furthermore, parents may react in multiple ways when they are informed that their child was involved in a bullying incident. Some parents may get upset, whereas others may deny the fact and, also, refuse to participate in any intervention program which aims at the improvement of their child's behavior, believing that this is a normal behavior to that age. So, parents should know that the school personnel take into serious consideration any bullying expression and its prevention, and that parents' cooperation and support are not only welcome, but also necessary.

Bullying incidents may be resolved more easily, if the school staff and mainly teachers can communicate with parents regularly and without any reservations. Parents should be immediately informed when a bullying incident occurs, if and in which way their child was involved and how this incident ended. They should also be informed if their child offered help, either by interfering or by asking help from an adult.

As there are many reactions of parents, it is important for teachers to understand parents' concerns and support their feelings when they discuss with them, in order not to make them feel offended. Preschool teachers may also reassure parents about the fact that bullying behaviors (which are not normal at that age as many people believe), will be eliminated more easily in the early stages of their manifestation rather than later, by following scientific methods and practices, whether their child is the victim or the 'perpetrator.'

In addition, teachers could organize workshops for parents to discuss topics related to pedagogical issues such as the development of their children's personality as well as their social

or emotional skills, etc. Information on bullying programs could be distributed to parents via brochures when the child is enrolled at school, sent by e-mail, posted on the school's website, sent by SMS or by using any other (appropriate) medium. Early childhood teachers and parents can gradually create a school culture that promotes the values of kindness, 'smooth' school and social inclusion, voluntary discipline, etc., supporting all children in their development. In general, parents should not listen to the word "bullying" only when it concerns their child.

Parents can help their children at home develop the important social skills they need to prevent bullying. Such skills are empathy, self-confidence and providence.

1. As mentioned above, *empathy* is commonly defined as the ability of a person to enter in another's position (Zangzouris & Purkos, 1997). Cole and Cole (2001) define empathy as the participation in the emotional experience of the other, while for Hoffman (2001) empathy is the ability of a person to perceive the feelings of others and to be able to experience the corresponding emotional state in which another person is located. Parents can therefore contribute to the development of their children's empathy by playing a more catalytic role in their nurture, since they constitute the cornerstone of shaping their children's personality. They can encourage them to express their feelings through verbal and nonverbal behaviors and help their classmates, by showing affection and kindness, as well as teach them to show good-natured and polite behavior both within the family and school environment.

2. Children should feel they are important, possess values and skills, be positive towards themselves and be able to overcome the obstacles that appear before them. If that happens, children will have acquired *self-confidence* skills. Parents play an important role in developing this skill, since at the very tender age of early childhood; children are still imitating the attitudes of their familiar persons. Therefore, parents should help their children know their personality and accept it as it is. They must set realistic, but also small goals and praise their children for what they have achieved. They could also entrust them with specific responsibilities at home, enabling them to feel useful. In addition, it is advisable to discuss with their children and listen to their opinions without judging their views and imposing on their own perspectives. Also, by not stimulating competition with their peers, parents encourage them to ignore possible challenges and stay cool during conflicts. Finally, they should advise children to react against the irrational demands of their peers by saying "no," support them express their point of view, encourage them to ask for help either from the nursery teacher or the school staff and motivate them to rely on their own strengths by showing self-confidence.

3. Beyond the development of the two above mentioned skills, children should also cultivate the skill of *providence*, that is, the ability to anticipate when an intimidating episode will occur to them or their peers. Parents could help their children develop this skill by encouraging them to think differently and find more than one solution to a potential problem. Thus, in case of a possible intimidating behavior, children may be able to invent alternative reactions and may also predict the consequences of these reactions. It is also helpful to advise their children against being simply viewers of an intimidating incident, but to help their peers by standing up and seeking for help, especially from the preschool teacher, whose intervention will be immediate. Therefore, the aim of prevention is to strengthen the positive and responsible behavior of children and correct the negative (Scott et al., 2007), in a reinforcing way.

SUPPORTIVE FRAMEWORK FOR CHILDREN WITH SOCIAL AND SCHOLAR INCAPACITIES

The most appropriate person to support parents whose children either intimidate or experience some form of intimidation, is the early childhood teacher. S/he is the person who should act immediately and resolve the situation in the case of a bullying episode. Early childhood teacher should discuss with pupils about their rights, the school's behavior rules, as well as the proper ways to deal with a bullying incident. S/he should also encourage children to express their anger in different ways, such as by painting or performing a role-play and not by injuring their peers physically or psychologically. S/he should advise pupils to be friends and/or reinforce the solidarity by developing teaching activities like those mentioned above. The early education educator should be present in all school areas so as to supervise the pupils, even during recess so as to prevent any intimidating situations.

Every country uses different management strategies to deal with school bullying issues. In some economically powerful countries, such as the United States of America, there is an organized system to address the phenomenon of school bullying. When an incident occurs, nursery school teachers inform the child's parents immediately, and, after a mutual agreement, the child is referred to a counselor for follow-up assessment. The counselor is the most appropriate person to conduct the Functional Behavioral Assessment (FBA), examining the classroom's environment and the stimulus which triggered the aggressive behavior. The counselor works directly with the child, only if parents agree, and after having studied his/her case, s/he may suggest strategies to help the child overcome the violent behavior. The preschool teacher, after studying the FBA's results, may refer the child for further evaluation to the school's special education department, which can identify the exact needs of the child, and is able to refer the child to even more specified services, such as speech therapy or psychological and emotional support, if necessary. Finally, under the federal law on the education of disabled people, a variety of intervention services is offered for children under 3 years old, and special educational services for children and young people with disabilities from 3 to 22 years old.

In Greece, as well as in other countries with similar status and features, there is evidence of surveys, which certify the increase of the phenomenon of school bullying and the effectiveness of direct intervention by both teachers and parents. Despite the evidence, the country lacks an educational policy for the confrontation of such phenomena from the Ministry of Education, Lifelong Learning and Religious Affairs. It is also missing an establishment of procedures to accurately record the incident and the recruitment of educated counselors who will be specialized in bullying phenomena, cooperate with parents, and supervise the preschoolers during the lesson and the recess. All educational institutions should also be equipped with professionals specializing in children's mental health, such as child psychiatrists, psychologists and social workers, as well as developing programs for the promotion of children's mental health that will be directly linked to the curriculum of the specific establishment.

In the United States of America a significant number of interventional programs for children with behavioral difficulties were recorded in the relevant literature, which could be implemented and have a notable impact. Some of them are:

- Function based intervention (FBI) (Kamps et al., 2011; Nahgahgwon et al., 2010; Blood & Nell, 2007; Lane, Kalberg & Menzies, 2009).
- Response to intervention- RTI) (Greshman, 2014; Lane et al., 2009; Maag & Katsiyannis, 2008).
- “Incredible Years” - The Incredible Years Teacher Classroom Management (IYTCM) Program (Webster-Stratton et al., 2011).
- Other approaches (ecosystem, humanitarian).

In Greece, none of the above programs are applied, because there is not any clear policy for addressing bullying by the Ministry of Education. On the other hand, according to Scanlon and Bamed (2013), even if one of them was applied, early childhood teachers’ beliefs would be an obstacle, as they may influence in a negative way the inclusion of preschoolers with problematic behavior into the school community. The success of all integration policies (Scanlon & Barnes, 2013; Goodman & Burton, 2010), is directly related to early childhood teachers’ views. If the teachers do not believe in the effectiveness of these programs and do not support them, then, certainly, even if these programs are implemented, they will not be efficient.

Concerning what was mentioned above, the contradiction that exists in the addressing of the phenomenon is clearly noticeable, despite having become incredibly widespread in recent years. Since there is not any formal and recognized intervention of the state to eliminate school intimidation, parents should often communicate with the school personnel, if they think that their child or another child bullies or is being bullied. If a preschooler is constantly being bullied or victimization, then all school staff should collaborate with parents and create a personalized intervention program and/or seek special counseling.

CONCLUSION

In conclusion, developing social skills is the most effective way to cope with bullying in both prevention and confrontation levels. The school environment under teachers’ responsibility and the family environment under parents’ control could be the best settings for learning social skills that would tackle school bullying, such as empathy, self-confidence, problem solving, and prevention. Various activities like those mentioned in this chapter could be developed in school and family environments. Moreover, both teachers and parents could use their experience and imagination to design and implement even more interesting teaching activities to practice social skills. School and family co-operation and collaboration could lead to the best possible results in preventing and dealing with school bullying for the benefit of all children, bullies and victims.

Chapter 33

LITERATURE AND NOVELS AS TEACHING STRATEGIES FOR VIOLENT COMMUNICATION AND EARLY CHILDHOOD BULLYING PREVENTION

Panagiotis J. Stamatis* and Evangelia G. Raptou

Department of Sciences of Preschool Education and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

Juvenile delinquent behavior appears in various forms in contemporary educational reality and it is known with the international term “bullying.” The aim of the present work is to inform and raise awareness of preschool children about the meaning and dimensions of violent communication and bullying, using novels for children, three of which are listed in this study. It is posited that quality child literary novels on the one hand provide the opportunity for a holistic and systematic view of the problematic behaviors that appear in the school environment and, in the other hand, propose strategies to prevent, detect and cope with these behaviors. Through narration, we argue that the children’s decision making may be positively influenced to prevent them from resorting to violent communication and bullying in their everyday lives.

Keywords: school bullying, violent communication, pre-school education, literature, novels, communication

INTRODUCTION

The term “bullying” proposed by Dan Olweus (1993) refers to a situation in which a student is being bullied or victimized when subjected to aggressive acts by one or more of his/her peers, when he or she experiences or causes unpleasant feelings or soul trauma, pain and discomfort that impede their psycho-emotional and learning development. Bullying is an asymmetric

* Corresponding Author’s Email: stamatis@rhodes.aegean.gr.

power relationship in which the victim is unable to react and defend him/herself. It is also a form of aggressive and violent communication that leads to the development of non-social behavior, which disrupts people's communication and sociability (Stamatis, 2013). Although school violence is mostly described as a kind of action, Besag stresses that (1989, p. 4) "bullying is the repeated attack - physical, psychological, social, or verbal - by those in a position of power on those who are powerless to resist, with the intention of causing distress for their own gain or gratification."

In this paper, we argue that the phenomenon of school bullying requires a systemic approach, in order to appropriately describe the variety of parameters (school and social) that are linked with the occurrence of problematic behaviors in schools. Problematic behavior is perceived both as a disharmony of the system and as a result of malignant social interaction, because the cause of the occurrence of problematic behavior is understood in the context of actions and interactions between participants in a particular environment. Furthermore, we draw upon the notion of emotional intelligence, which may be defined as the "capacity for recognizing our own feelings and those of others, for motivating ourselves, and for managing emotions well in ourselves and in our relationships" (Goleman, 1998, p. 4). In this context, we posit that literature - and especially children's literature - offers mediated experiences with teaching content, thus positively contributing to the cultivation and the development of emotional intelligence, which is a basic prerequisite for acquiring communicative and social skills, especially in childhood and for shaping children's personality. In specific, Allen (1999) noted that child literacy is an ideal source of help for children's feelings' management, because books are a way to deal with sadness, to manage destabilizing differences and gain self-esteem. Hence, literature excerpts may help the children in developing the five main elements of emotional intelligence, namely self-awareness, motivation, self-regulation, empathy and adeptness in relationships. When the excerpts are appropriately written, they allow children to identify with heroes and help them to comprehend complex things at the same time when they young children try to adapt to the unexpectedly complicated process of growing up.

PURPOSE OF THE STUDY

The purpose of this study is to employ novel narration of literary texts written for preschoolers and children of early childhood, in order for the teachers and/or parents (in the role of narrators) to facilitate the children's appropriately dealing with violent communication and bullying in their everyday life. The aim of this study is to present an exemplary way of using literature to address antisocial attitudes with communication skills development and to suggest "phillanagnosia" (one's desire for reading) as an excellent medium for growing spiritual culture and social sensitivity (Raptou, 2017). Qualitative literary works, by which the phenomenon of violence in the school, family, and/or social environment is approached, are supportive strategies to detect and prevent this phenomenon.

In the present study, bullying is approached from the perspective of children's literature as a result of the existence of violent communication in interpersonal relationships. The risk factors contributing to its occurrence and the time of its first appearance are examined, in order for early intervention in preschool children to be allowed. This work focuses mainly on preschool education because, according to the literature, at that age children are able to develop

friendly relationships and acquire interpersonal communication skills more than at any other age of their lives (Stamatis, 2015). This age also allows the learning and promotion of specifically expected behaviors and the development of social skills, the lack of which is the cause and the consequence of the children's involvement in intimidation and victimization situations (Crain, Finch & Foster, 2005; Keller, Spieker & Gilchrist, 2005).

Moreover, the above-mentioned relationships begin to form at that age and be more complete at an older age. The simple plot and rough description of characters and behaviors is, in addition, an appropriate means for familiarizing children with literary content and making them smoothly assimilate the moral-teaching message it encompasses. Therefore, the present work provides the basis for preventively tackling the problem of school bullying, which is considered as a form of communicative violence existing even in the pre-school environment, combined with a variety of racist, xenophobic or homophobic perceptions. Through literature and novels, the children practise identifying and analyzing the emotions of engaging in intimidating incidents and in skills' learning to actively cope with bullying incidents in education.

METHOD

In order for the aim of this study to be achieved, the content analysis of three Greek child novels was used as the basic research method. The novels are an exemplary sample of similar literature works written and/or read by children, teachers or parents around the globe. Content analysis was chosen, because it is a method of indirect observation of social phenomena, with the ultimate aim of interpreting the written or verbal discourse, namely the analysis of social communication, its extensions and its consequences (Mukherji & Albon, 2015; Cohen, Manion & Morrison, 2011). Content analysis is linked with the categorization of the data, which is a prerequisite for the method's success, since the categories include the essence of the research. The greatest difficulty of the present study was the creation of a limited number of categories, in order for important conclusions to be reached. A second difficulty, which exceeded the first one, was the different way in which each of the three novels examined in this study, presented the phenomenon of bullying and its consequences. The categorization, which was finally chosen, determined the structure of the study of novels, the abstracts of which are presented below. All of them show in a different way some similarities related to the violent communication and bullying in educational environments.

ABSTRACTS OF THE NOVELS

Abstract I: "Together" by Eleni Priovolou

This novel refers to social racism, as experienced by a group of children in a neighborhood and in a school. Myron is the victim of a child gang called Beetles. For those children, Myron was the mosquito, the short, the tender donut and, thus, the perfect victim, because he was different in his soul and habits from the Beetles' members. One day, Luna appears in Myron's life, changing everything. As she was also a victim of social racism, mainly because of her dark

skin color, she does not accept Beetles' behavior passively, but she struggles and raises her courage, against those who fight her. Luna and Myron's joining their strengths offered the other children different lenses to see the world and to start walking on the right path; for example, this happened for Vanda, who initially judged people by their skin color, but finally she learned that there were many white people with a "black" heart, meaning the evil people. Actually, both the content and the spirit of this novel are against any prejudices, which garner violence and bullying.

Summary II: "Peter's Girl" by Argyro Moutzaki

The novel titled "Peter's girl" is a story that combines incidents of school bullying and racism. Alisa is the protagonist of the novel. She is a very beautiful fourteen-year-old Pakistani, who had recently arrived with her family in Greece. As she does not speak Greek, she has difficulty in fitting in her classroom and starting a new life. Her parents and her seventeen-year-old brother make a living by doing manual labor jobs. Alisa is Peter's best friend, who is a very good child of a middle-class Greek family. Greek girls are outraged, because Alisa, a foreigner in their class, attracts Peter's interest. Among all girls, Lucia is the most furious. She is a Greek girl, who will soon immigrate with her family to another country. She is outraged, because she believes that Alisa's parents took her parents' jobs. Lucia attacks Alisa, who does not talk, because she is ashamed, scared, and does not want to embarrass her parents. This gives her a great deal of sadness, until one day she finds the courage to speak. After that, her difficulties are gradually softened with some adults' help.

Summary III: "The Hard Nut" by Eleni Svoronou

Aisa is the name of a nine-year-old refugee girl from Afghanistan. She is one of the millions of refugee children, who abandon their country, home, school, and friends every year, alone or with their families, in order to save themselves from war and violence. Aisa has been found in Athens with her mother and brother, where the living conditions are difficult, as there are many shortcomings, long and lasting uncertainty. She feels stressed about her father, who is not with the rest of the family. Aisa goes to school, but the other children are cautious and display an arrogant contempt for her. Aisa, as a hard nut, chokes back her tears, gives her battle and wins it. The heroes of the novel are Aisa's Greek classmates. All of them are children growing up in a country that experiences the consequences of a deep financial crisis. They are children, who must also deal with the difficult reality of refugee life. The Greek children are called to get ahead of themselves and to support their refugee classmates; they are called to accept their peers by overcoming the racist stereotypes and the xenophobic prejudices.

RESULTS

The approach of violent communication and bullying through literature refers to the method of *bibliotherapy*, which emphasizes the employment of realistic narratives with

veritable heroes that are closer to the students' everyday life and their problems. Russell and Shrodes (cited in Silverberg, 2003, p. 132) define bibliotherapy as "a process of dynamic interaction between the personality of the reader and literature--an interaction which may be used for personality assessment, adjustment, and growth." In general, narratives can work proactively and therapeutically, contributing to the cognitive understanding and emotional experiencing of complexity of such a complicated phenomenon, as the phenomena of violent communication and school bullying are (Tinker & Wilson, 1999). The benefits of reading books are generally the emotional and spiritual development that children gain according to Goddard (2011, p. 57), who claims that "[r]eading to children is central to their development. Books provide a safe medium for children to explore different concepts, feelings, and attitudes while allowing them to better understand their environment, community, and societal expectations. Reading to children increases self-esteem, gives comfort, and may aid children in coping with difficult situations." In particular, the benefit of reading children's literacy books is the fact that it promotes the young children's ability to identify with the hero of the novel, who may face similar problems. Identification with the novel characters and emotional engaging with them operate as a teaching issue which allows or encourages the children to use similar ways for addressing the problems that they encounter.

In the framework of bibliotherapy, reading novels can be a strategy for developing interventional actions within the school unit, where the participating children, whether consciously or unconsciously identify with the heroes, they become producers and expressers of personal thoughts and feelings, they make judgments and, ultimately, assessments that gradually turn into life stances and attitudes (Gregory & Vessey, 2004). The main purpose of these interventions is for the children to be informed about the various aspects of violent communication and school bullying, as well as for the improvement of the emotional and social development of the children, as a result of their participation in a "realistic story of intimidation," namely the creation and development of feelings related to solidarity, empathy and mutual-protection. In the novels being studied in this chapter, the heroes seem to be real, they act in environments that are very similar to the situations the children experience in their familiar school environment, and, therefore, the children-readers experience the situations mentioned in the novels as simulation situations, in which they are called upon to develop social skills (such as conflict management and development of a friendly school climate etc). It should be stressed that all those who either directly or indirectly participate in school life have shares of responsibility for the quality of the school climate, by developing a multitude of interpersonal interactions within their daily communication relationships (Stamatis, 2015).

Moreover, the narrative techniques contribute to the development of the reader's empathy. The third-person narrative, sometimes autonomous, as in the novel titled "Together," sometimes alternating with the first-person narration, gradually reveals the story (as is the case of the other two novels examined in the present study). At one time, a neutral and omnipotent narrator and, at another time, the inner perspective of the participants in the novel's story, both enable the reader to enter the children's psychological world and to face the events through their sharp and innocent glance. The alternation of narration from first to third person attempts to outline the subject from a dual perspective and shows things with greater realism. The originality lies in the fact that the novel story of Alisa, a Pakistani girl who attended high school lessons, is mainly portrayed through the first-person narration made by a little girl, called Alkmini, Peter's sister, who is one of Alisa's classmates.

The contribution of the novel's illustration is as important as their content. The imaginative and purposeful pictures animate the heroes, embellish their expressions, complement and point out Alisa's story in the best possible way in the novel "Peter's girl." The intense, harsh and dark colors and deep reds of the images mostly convey the climate and color of Afghanistan, the country of Aisa in the novel titled "The hard nut." Boys and girls dressed in dark colors, headscarves wrapped in girlish faces, seem to be the means to claim the right to live, play, coexist and accept diversity by the classmates within the school area. Appropriate illustrations dynamically highlight the longstanding problem of people's acceptance, coexistence and living together with the diversity created by refugees, forced immigration and the violent expatriation of people.

The three children's novels examined in the present study are points of encounter with the current multiculturalism of the Greek classroom, because, as noted in "Peter's girl": "Many things in life function as a circle. At the place we stand, someone else will stand after a while. Everything changes rapidly" (p. 75). Multiculturalism refers to a state of coexistence of many nationalities, while interculturalism refers to the approach of this situation, drawing upon the experiences of all those living in the same country: local residents and immigrants. Intercultural education aims to improve social cohesion and justice. It targets, as in the case of literature, at the cultivation of respect and the development of positive attitudes among people of different ethnic, cultural and religious background. Furthermore, it improves the pupils' ability to look at the educational and social phenomena from the perspective of different cultures and not only from the predominant one (Govaris, 2013).

In all three children's novels examined in this study, the main forms of violent communication and school bullying were identified, namely: (a) verbal bullying; revealed by mockery and insults, (b) indirect, social and relational bullying; manifested by social isolation, crowd exclusion and group manipulation, (c) extortion, (d) visual bullying; revealed with offending notes, (e) digital/cyberbullying; emerged with the use and exploitation of internet technology and mobile phones, (f) discrimination based on gender differences, (g) discrimination; based on ethnic origin which constitute manifestations of racist treatment of immigrants and refugees. The three parameters that distinguish bullying from aggressiveness, according to Olweus (1993), which are the unnecessary or unprovoked aggressive individual or group behavior, the repeatability of behavior and power imbalance among the bully and the victim, were also identified in this study.

As a result of the holistic view of violent communication and school bullying, the representation of the role of the children involved in these phenomena is precise. Thus, through the heroes of the three novels examined in the present study, the classical profile of the victim and the perpetrator is met, as noted by Kourakis (2009): (a) the perpetrator - usually a boy - appears as a person having physical strength; a person distinguished for his athletic performance; a person who is provocative against others with a tendency of domination; a person that does not obey the school rules, who uses violence to resolve differences, gaining satisfaction of such behavior, ignoring the problems of others, (b) the victim appears as a weak person and with strong features of ethnic or religious diversity. Despite the fact that the victim usually experiences anxiety, unsafety, diminished self-esteem, introversion and is not encouraged to defend himself/herself or (s)he is seeking for others' help, the protagonists-victims of the examined novels show a dynamic character, which is capable of reacting and overtaking traps set by the protagonists-bullies. They are capable of defending physical power with the power of mind and of a value-based moral system. This model confirms the primary

role of the family in shaping the personality of the child and underlines the negative impact of the lack of effective communication between children and their parents (Rivers, Duncan & Besag, 2009).

The study of all three novels confirms Olweus's (1993) assertion that school bullying has quantitative and qualitative gender differentiations, as boys are more physically attacked than the girls, while the girls are more verbally and psychologically attacked than the boys. Girls having few friend become victims of indirect and intimidating behavior, while boys are exposed to direct intimidation. For all the heroines of the examined novels, their being girls and their having different ethnicity is combined with their different physical image, thus constituting a profile that may attract school bullying. The study of the examined novels highlighted the traditionally dominant stereotype of masculinity that wants boys to have masculine features, strong and sizable body, to avoid to express emotions, to show limited empathy and to behave dynamically, in order to seem distanced from any kind of dependence. In addition, they successfully participate in sports, as in the case of the bullies described in the novel entitled "Together," who manage to keep their balance on skateboards and to achieve impressive, versatile and dangerous maneuvers, demonstrating, on the one hand, exceptional athletic skills and, on the other hand, strength and toughness both identified with bravery, which symbolizes an implicit predominant masculinity.

The narrative revelation of violent communication and school bullying taking place in the novel titled "Together," considered by a systemic point of view, is in accordance with Vreeman and Carroll (referred in CASEL, 2009, p. 6), who in their systematic review of school-based interventions designed to prevent bullying, concluded that "The most effective interventions typically use a whole-school approach consisting of some combination of school-wide rules and sanctions, teacher training, classroom curricula, conflict resolution training, and individual counseling. Anti-bullying programs exclusively directed at the bully, the victim, or both, without involving other students or addressing larger school climate issues, are less likely to be effective." In all the examined novels, a whole school approach to violent communication and school bullying is observed, since the interest is not only focused on the individual level, but also on the class level, or even at the school unit level. In the novel entitled "Together," the basic representations of these phenomena are revealed, which could be part of a school-activity program for the development of the children's communication skills, in the sense that: (a) the positive relationships among pupils should be promoted, b) the good relationships between teachers and students should be promoted, and (c) a clear and comprehensive teaching on emotions, socio-emotional skills and management of difficult and adverse conditions should be conducted. Similar activities fall within the field of Communication Education, which opposes violent communication to school bullying in a variety of ways and practices (Stamatis & Nikolaou, 2016).

The attitude of the professors described in the novel entitled "Together" confirms the basic principles mentioned by Olweus and his colleagues about the phenomenon of school bullying (outlined in the Bullying Prevention Program; Olweus et al., 2007), according to whom care should be taken of: "(1) warmth and positive interest and involvement in the students' lives, (2) firm limits to unacceptable behavior, (3) use of nonphysical, non-hostile negative consequences when rules are broken, and (4) functioning of adults as authorities and positive role models." In addition the factors that positively contribute to warm school climate conditions according to Cefai (2008, p. 38-39), are "The school climate, staff relationships and relationships with parents are other important influences on classroom relationships" and "care,

solidarity, collaboration, acceptance and celebration of diversity are the key values underlining pupil behavior in the classroom. Pupils care for and support each other and work and play together. They solve conflicts amicably and constructively. Instead of competing with each other, they help each other with their work. Supporting one another is a celebrated classroom value.”

These fit nicely with what may be inferred to be in the mind of the teacher, when at the end of the novel titled “Together,” she encouraged all the pupils to be engaged in theatrical activities, employing at the same time the “method of reconciliation,” a method applied to English pupils and proved to be effective, because it brings in contact the bully with the victim making them feel that they belong on the same side (Cowie & Jennifer, 2008). In the novel entitled “Together” more particularly, all those characters involved in school bullying - bullies, victims, bystanders, guardians, teachers- are outlined and the strategy of coping with the phenomenon of school bullying is presented in an impressive way, which is the essential communication among all members of the school community. The writer herself stresses: “I do not really believe there are bullies and victims at these tender ages. The child who will be delinquent is also the same victim of social and especially family circumstances. A child when he or she is accepting or living with family violence is more likely to be violent than a child who does not receive the right attention and acceptance from the family environment. Therefore, as much as one side has the need for support, so much has the other one.”

The reading of the three novels examined in the present study is posited to help the readers to learn problem-solving strategies within the school environment, as well as to learn about appropriate conflict management practices related to violent communication and school bullying. In this way, it is understandable what McGrath and Noble (2016, p. 38, 31) noted: “*a positive school culture is characterized by positive student peer relationships, positive student-teacher relationships, positive staff relationships and positive family-school relationships*” and that “*clear classroom and school rules against bullying that are consistently enforced and restated.*” Considering the international relevant literature and particularly the studies aimed at designing effective interventions to reduce the phenomenon of school bullying, it seems that their aims are to raise the pupils' awareness of the dimensions of the phenomenon, of the seriousness of the issues at hand and of the mechanisms that support the phenomenon. They also aim at the students' reflection on their conscious or unconscious involvement in intimidation incidents, as well as on the communication improvement among all those working within the school unit, by developing behaviors and actions that contribute to a creative resolution of all raised problems and by showing respect and acceptance to others. In this way, the improvement of the school climate is being secured (Mauss et al., 2011; Elliott, 2002).

Knowledge of all aspects of school bullying and the development of skills for finding some ways to approach the bully and the victim or other effective practices of tackling school bullying incidents is achieved through the teaching of literature, because some literature's outcomes are similar to those of teaching goals. In this way, a safe educational environment is established, as the rules that are established, exude a sense of justice and contribute to the development of a climate of cooperation and a culture of dispute resolution with reciprocal concessions and a spirit of mutual respect.

In conclusion, the readers of any age, who read novels referred to violent communication and school bullying, whether they are children, parents or teachers, are becoming sensitive to these issues, as they recognize the roles of everyone involved and they develop: the ability to search and find the causes that contribute to the production and reproduction of the

phenomenon, the ability to cultivate attitudes and behaviors against school violence of any kind, and the ability to raise resistances by letting each one of the involved ones choose his/her own strengths and powers. At the same time, the children, entering the psychology, the reflections and the thinking of the heroes of the novels (victims, either as bullies, victims and/or observers), can develop social skills, empathy and emotional maturity. Moreover, they may recognize the need to adhere to the school rules, as well as the importance of disciplined behavior for the smooth functioning of the school community. Modern school units may be conceptualized as “learning organizations,” in the sense that those living in an organization “learn,” i.e., they acquire the ability to realize a cognitive meaning or experience (Senge, 2006). Within this framework Cefai and Cavioni (2014) are based on Adi’s et al. to report that “in a systematic review of the effectiveness of promoting social and emotional well-being in primary school, the most effective interventions were multicomponent programmes, which covered classroom curricula and school environment, together with programmes for parents... while identifying the needs of children who may need within-school support as early as possible” (p. 24). On the one hand, the fictional approach to school bullying cognitively and emotionally strengthens the children involved in bullying incidents and, on the other hand, it strengthens those who do not know and participate in any role in intimidating incidents, helping them to enter a simulation environment, in which their interpersonal relationships and their ability to effectively deal with aggressive behaviors are tested (McLeod, 1997; Crompton, 1991). Teachers and parents should work together to actively and effectively support the efforts of the children, especially those in their early childhood.

CONCLUSION

The content analysis of the three examined novels that formed the subject of this study, led to interesting concluding statements, as summarized below.

- 1) The approach of pupils-bullies by a school teacher, in collaboration with pupils-victims or pupils-bystanders aims to understand intimidating behaviors, empowering empathy for expressing and obtaining effective solutions, stemming from collaboration and communication among all school members.
- 2) The psychological support for victims occurs in a similar fashion, as the one indicated by relevant research. It concerns education about the development of assertive behavior aimed at expressing positive feelings, expressing negative emotions, setting boundaries, and developing a child's initiative, to strengthen self-confidence, while, at the same time, the child demonstrates respect for the rights of his/her peers.
- 3) The important role of the bystanders, which in the examined novels plays a major role on communication, is emphasized, as the discouraging and the stopping of bullies by the bystanders, depriving them of “the admirers or the fans,” thus resulting in their stopping their aggressive behavior, by building positive student-peer relationships.

Literature seems to be a major ally for the timely treatment of violent communication and school bullying, which threatens the coherence and functioning of school units and,

consequently, the education system and the society as a whole. As the field of communication increasingly takes up a larger area in the educational process, the communicative use of novels is highly recommended. Through novels' reading, it is posited that the communication violence at schools will progressively decrease, especially at the early stages of the vulnerable preschool age, where most children, as they are unsuspected and unprepared, do not know how to deal with such aggressive behaviors.

Chapter 34

SOCIAL ANTECEDENTS OF BULLYING: WHEN DOES PEER INTERACTION BECOME INTERPERSONAL REJECTION?

Anna Polemikou^{*}

Department of Preschool Education Sciences and Educational Design,
University of the Aegean, Rhodes, Greece

ABSTRACT

The boundaries between bullying and a spectrum of other forms of intersubjective engagement (i.e., teasing, jocular mockery) are often hard to discern. As they grow up, children mostly exhibit social behaviors that are commonly accepted as an inherent part of their development. However, they may also engage in maladaptive behaviors that convey highly ambiguous or inappropriate connotations, and are often much harder to identify. Research suggests that the precursors of bullying appear during early childhood and need to be addressed soon thereafter. If left unattended, childhood aggressiveness is known to steadily escalate into life-persistent developmental trajectories of aggression in adolescence and adulthood. It is therefore important for parents, counsellors and educators to be able to determine whether the ways that a child engages socially are essential to his/her early development or whether they carry serious implications for his/her emotional well-being and that of their group of peers, in order to intervene accordingly. The present chapter explores the human capacity for intersubjectivity as a means of becoming aware of relational interactions that involve bullying in the making, and promotes preemptive educational roles in shaping prosocial contexts and events in early education.

Keywords: intersubjectivity, intersubjective engagement, aggression, teasing, tickling, bullying, preschool, early childhood education, bullying prevention, peer interaction

INTRODUCTION

“A child whose leg is broken playing football is not an abuse victim;
a child whose leg is broken by being beaten is.
It is not the injury but the message it conveys,
the meaning of the injury that matters.”

~ James Gabarino, 2011, p. 927

During the past 30 years a particular form of interpersonal aggression has been the focus of theoretical and empirical attention among school professionals, mental health specialists and educational researchers, and widespread debate from media and the public. The phenomenon, commonly known as “bullying,” refers to a specific manifestation of aggression that involves a power imbalance between perpetrator and victim, and is characterized by repeated aggression over a prolonged period of time (Lansford, 2018; Volk, Veenstra & Espelage, 2017).

Bullying has been described as a human rights violation of Article 29 of the United Nations Convention on the Rights of the Child’s (The United Nations, 1989) statement, according to which education shall be directed to: “the preparation of the child for responsible life in a free society, in the spirit of understanding, peace, tolerance, equality of the sexes, and friendship among all peoples, ethnic, national and religious groups and persons of indigenous origin.” Hence, it is the right of all children living in our global society to receive an education that cultivates positive attitudes and promotes socially acceptable ways of behaving, in lieu of dominance-based practices of aggression, bullying or harassment (Pepler & Craig, 2009).

The harmful effects of bullying on the development of children have been repeatedly reported at length in the literature and cannot be overstated. Bullying has been associated with maladjustments for both victim and perpetrator that manifest, amongst others, as difficulties in relating, low self-esteem, and prolonged mental health problems such as depression and anxiety (Kirves & Sajaniemi, 2012; Card, et al., 2008).

Although bullying has been extensively studied in the context of primary school settings, until recently only a few studies had investigated the phenomenon amongst under-school-age children. Nevertheless, accruing evidence suggests that bullying occurs systematically in preschool and kindergarten environments (i.e., Repo & Sajaniemi, 2015; Kirves & Sajaniemi, 2012). For a multitude of reasons the term appears to carry particularly problematic connotations when toddlers and preschoolers are involved and –understandably, as we will see next– has been controversial.

EARLY CHILDHOOD BULLYING: THEORETICAL AND EMPIRICAL CHALLENGES

Before we attempt to identify aggressive behavioral manifestations as bullying, there are several points that need to be considered. The key problem in this approach revolves around reservations on how to interpret bullying in a way that is suitable for children of such a young age (Cameron & Kovac, 2016; Repo & Sajaniemi, 2015). Aggressive behavior emerges early in life, follows a normative developmental expression, and is a fairly typical response to various forms of intrinsic or extrinsic hurt or frustration. Most children have had their onset of physical aggression (e.g., hitting, smacking, kicking, biting) between the end of the first and the

beginning of the second year after birth. In terms of their frequency, aggressive episodes increase overall during the first 30 months (as the capacity for self-regulation and inhibition is still in the process of being modulated) and decline steadily thereafter (Lansford, 2018; Alink et al., 2006; Côté et al., 2006).

In light of this information, how does bullying sit within the broader context of early childhood aggression? In trying to define aggression, one discovers that it has been broadly covered in the literature of both lifespan development and abnormal psychology. Consequently, aggressive expressions include a set of behaviors that range from typical and adaptive to atypical and maladaptive (Keenan, 2012). For the purposes of the present discussion, early aggression is defined according to Shaw and colleagues' (2000, p. 398) description as an "act directed toward a specific other person or object with intent to hurt or frighten, for which there is a consensus about the aggressive intent of the act."

Given the large and growing body of research on this topic, it may come as a surprise that it remains unclear whether bullying and more generalized peer aggression constitute distinct or overlapping constructs (i.e., Ybarra, Espelage & Mitchell, 2014). The general consensus situates bullying within the broader literature on aggressive behavior, indicating the former as a discrete subcategory of the latter (i.e., Repo & Sajaniemi, 2015). However, this is by no means universally accepted, which reflects the difficulty in sorting out an array of related behaviors based on criteria such as age, context, structure, intention, etc.

It has been commonly reported that preschool children who manifest high levels of physical aggression face a higher risk for continued disruptive behavior and are in need of specialized clinical services (Tremblay, 2012). For some researchers these cases constitute circumstances of atypical aggression, which they consider secondary to an array of other deficits or developmental delays (e.g., Keenan, 2012). For others (e.g., Hanish et al., 2004) an increased frequency of physical aggression in comparison to one's peers, is enough to fulfil the criteria of bullying, which raises the next question: Does early childhood bullying differ from generalized manifestations of atypical aggression? And, if so, how? For the time being, the answer to this question is diverse. Because of the limited definitions of bullying among preschool and kindergarten children, it is highly likely that the phenomenon is not being accurately depicted in the literature, neither in prevalence nor in form.

Firstly, with regards to prevalence, there are concerns of bullying being either over- or under-reported, both of which have disadvantages. Exaggeration may lend itself to a self-fulfilling prophecy, according to which an increased prevalence is expected, and ultimately produced. Moreover, ethical considerations dictate the conservative use of developmentally inappropriate labels or concepts when dealing with children. Any premature stigmatization should be avoided at this very impressionable age, as preschoolers are likely to internalize and incorporate it in their identity and sense of self-worth, which is why the term 'aggressor' is occasionally preferred over 'bully' (Repo & Sajaniemi, 2015).

On the other hand, undermining the aforementioned prevalence immediately excludes important forms of serious bullying that may be characteristic in this particular segment of the population. It is not uncommon for adults to trivialize the first signs of inappropriate behavior in small children, thus failing to recognize the underlying threats of ambiguity, confusion, and emotional discomfort. Sweeney and West (2001) suggest that stereotyped views of bullying are not unlikely among a significant proportion of teachers who tend to equate bullying to physical assault, and to disregard non-physical acts as a means of inflicting harm.

This view was further corroborated recently by Cameron and Kovac (2016), who compared parents and childcare workers in their belief that verbal aggression is an indicator of bullying. Interestingly, parents were more likely than professionals to support this perspective, something that children also endorsed by rating practices such as name-calling and teasing as more prominent in their experience, followed by physical assaults and isolation (Sweeny & West, 2001). These findings highlight the subjective nature of bullying in one's licence to take offense, and the importance of approaching the topic from the viewpoint of preschoolers themselves, instead of assuming traditional definitions of bullying and applying them indiscriminately to all ages, settings and circumstances.

As a child prepares to enter kindergarten, emerging skills of communication and emotion regulation appear to influence the trajectory of physical aggression which gradually declines in frequency around the 4th year of life. This coincides with the termination of unfocused temper tantrums (i.e., kicking and throwing objects in defiance; typically appear during the second year after birth), but also with the time at which the amount of aggression that a child displays reaches its peak (Côté et al. 2006; Hartup, 1974). Interestingly, between the ages of 4 to 7 years, children show a marked increase in the frequency of bouts of indirect aggression, which gradually introduces a range of other forms such as covert, relational, and social aggression (Card et al., 2008) as they grow older.

Insofar as traditionally defined bullying is concerned, contemporary research suggests that children starting from 3 years of age have the potential to bully, which renders bullying relevant to preschool-aged children and constitutes a severe problem for the kindergarten environment (Cameron & Kovac, 2016; Repo & Sajaniemi, 2015; Kirves & Sajaniemi, 2012; Monks et al., 2009). Yet, even at this early age, the act of bullying follows a natural progression; it does not suddenly and mysteriously appear full-blown among children, but rather escalates from physical, to a more 'figurative' aggressiveness (i.e., related to assertiveness and drive) towards a deliberate, dominance-based pattern of maladaptive aggression.

The idea that physical aggression is initiated through modelled learning is widespread, but not everyone accepts the accuracy of this statement. For example, the universality of rough and tumble play seen in preschoolers is not a product of learning (Reebye, 2005). Likewise, Donald Hebb (cited in Tremblay, 2012) used the paradigm of temper tantrums to illustrate this point, stating that they are not produced via any means of imitation or learning. In reality, the opposite is true; children learn how *not* to be physically aggressive rather than the other way around.

Contrarily, for the most part, habitually expressing aggression as a disorder (bullying), happens when the child observes and imitates the practices of others, or when it becomes aware of his/her own self-assertion and displays of power over another, in the context of trying to get what he/she wants. Witnessing violence in their homes or neighborhoods, being maltreated, or being exposed to aggressive content through the media, are all risk factors of learning to use deviant patterns of aggression (Reebye, 2005). As small children enter early educational settings, they bring with them a history of experiences from their parents, siblings, peers, media and community. Although most will have learned to inhibit physical aggression and use alternatives by school entry (Tremblay et al., 2004), these experiences prepare them to be more resilient or more prone to engage in bullying-related behavior.

If early interventions succeed in targeting young children at a high risk of aggression, one should expect atypical aggressive inclinations to remain short-lived and childhood limited (Cameron & Kovac, 2016; Repo & Sajaniemi, 2015; Tremblay et al., 2004; Tremblay et al., 1999). Alternatively, aggressive displays are highly likely to turn into prolonged and life-course

persistent patterns of disruptive behaviors that systematically violate the rights of others. This is the primary reason why preventive practices in early educational settings are so important (Huesmann, 2018).

PAINTING A SHARED REALITY THROUGH INTERSUBJECTIVE ENGAGEMENT

As we already explained, aggression can be understood in various ways, some of which are seen as a natural part of growing up, some serve adaptive functions, some are secondary to other (e.g., developmental) disorders, and some pertain to maladaptive forms of social exchange. Setting a point of departure between bullying and other forms of aggression in preschoolers and kindergarteners is a rather challenging prospect, that could be very illuminating when it comes to fully understanding the broad spectrum of functions related to expressions of aggression.

Yet, more often than not, it is the *shared meaning* between the agents that defines the quality of the outcome of their exchange, rather than the content or the structure, or even the underlying intention itself. This idea proposes an alternative set of assumptions with respect to bullying, that reject the structural confinements of behavioral manifestations, and instead emphasize the *shared process* between those involved in the interaction. This approach allows a wide spectrum of aggressive behaviors not only to be identified by those present but, more importantly, to be *co-created*; This is an important breakthrough in our view of bullying, which allows educators to assume proactive (instead of their traditional defensive) roles in managing the situation.

The topic of intersubjectivity can be traced in the works of Edmund Husserl, founder of the philosophical movement of phenomenology. Phenomenology is a term used to describe how consciousness shapes one's perception of the world. Husserl advocated a process-bound foundation of life, and announced phenomenology as a method of philosophical exploration through which the person's embodied experience could be revealed. He posited that the immersion of the individual in the immediate system of his phenomenology brings to the forefront immeasurable observations and insights that would have otherwise diminished or remained obscure (Polemikou, 2016). In other words, in the context of schooling, a phenomenological approach validates each child's perspective and version of reality, based on his/her experience of ongoing events, and supports the idea that everyone has legitimate reasons for behaving in a certain manner.

Intrinsic to phenomenology is the topic of *intersubjectivity*, which refers to the sharing of subjective (i.e., phenomenological) states by two or more individuals. Husserl argued that intersubjectivity, or 'other-awareness', represents a need to experience the world as available not only to oneself, but also to the Other. In turn, the experience of the Other is needed for the development of one's own experience (his/her self-awareness). As a result, in the educational framework, antisocial aggression may be seen as an inappropriate communication pattern between individuals who carry different perceptions, experiences, and versions of reality.

The bridge between these two experiences, between the personal and the shared, the self and the others, provides a means of experiencing and 'co-creating' the objective world. This provides an opportunity to reframe or to change a failing communication pattern from

something ambiguous, alienating and hostile, to something more secure, inclusive and functional. Thus, *intersubjective engagement* refers to a variety of human interactions that may take place between two or more individuals, who share a set of matched or shared mental states.

CONCOMITANT FORMS OF AGGRESSION: THE TEASING PARADIGM

A form of aggression that has been found to be strongly interrelated with bullying is the practice of teasing, although the two can be very distinct acts with different motivations, goals, and outcomes (Mills & Carwile, 2009; Sweeting & West, 2001). Teasing can be defined as an intended or deliberate (i.e., done with awareness of the implications of what one is doing or saying) behavior, which is goal-oriented or strategic (i.e., done to achieve something) –in this case, to challenge (either verbally or via non-verbal means) a distinctive attribute of the recipient.

At a relational level, the difference between concomitant acts, such as teasing and bullying, is often sorted out intersubjectively; there is enough contextual information and ingroup knowledge enabling the recipient(s) to disambiguate whether an act is being presented in a funny/playful frame, or in a mean/alienating frame.

This idea presents enormous pedagogical prospects in the educational setting, where school professionals can invest in intersubjectivity in order to prevent and/or reframe a series of ambiguous events and behaviors (Haslebo & Lund, 2015).

A state of “intersubjectivity” during a particular instance of peer interaction, such as teasing, dictates that an agreement exists between the persons involved on a given set of meanings or definitions of a particular situation. According to Zlatev and colleagues (2008, p. 2) it is a uniquely human capacity which entails “the sharing of experiential content (e.g., feelings, perceptions, thoughts, and linguistic meanings) among a plurality of subjects.” In the act of teasing between peers, this would mean that both parties are in mutual agreement of the context in which this exchange is taking place, and are co-creating the interaction.

Teases are often used to convey messages that may seem negative or hurtful towards a recipient, but in a way that suggests the opposite (Hendry, 2016). The producer in question maintains an ambiguous or ambivalent tone with regards to his or her intentions, which is the direct result of a combination of expressed jocular and aggressive attitudes (Almenara & Jezek, 2015). In light of this view, it is expected that teasing is not meant to represent a harmonious interaction; instead, it initiates various levels of tension and conveys aggressive intent.

As suprisingly complex and ambiguous form of interpersonal communication, teasing can be a taxing and challenging aspect of human interaction for young children to grasp and to negotiate (Harwood & Copfer, 2014), which is exactly the point that Daniel Stern (1985, cited in Reddy & Mireault, 2015) makes by claiming that “you can’t tease another person unless you can correctly guess what is in their minds and make them suffer or laugh because of their knowing.” Similarly, Haslebo and Lund (2015, p. 174) state that “What happens after an act helps attribute meaning to the act,” thus stressing the importance of a reciprocal experience that is characterized by a shared meaning.

At an implicit level, the dynamics of teasing serve much more far-reaching goals, amongst which a way of evaluating either a person's reactions, tolerance or the coherence of a system (Reddy & Mireault, 2015). Hence, perhaps it is no coincidence that teasing tends to happen

during interpersonal spaces of neutrality or boredom, thus serving as an intense way of inviting the recipient to social interaction.

It appears to be the case that teasing is an ambiguous social skill of paradoxical nature in more aspects than one. First of all, it is risky in terms of the reaction (friendly-pleasurable, neutral, negative) that it may evoke (Shapiro, Baumeister & Kessler, 1991). In actual fact, teasing leads to polarized expressions of attachment between the parties involved, by either creating or strengthening a conflicting sense of loyalty or by causing a rupture to pre-existing social bonds. In other words, teasing can either carry prosocial (i.e., playful, affiliative, humorous, affectionate etc.) or antisocial (i.e., demoralizing, embarrassing, hostile, etc.) messages to the recipient (Jones et al., 2017; Smith et al., 2010).

There is no denying that playful teasing is a sort of precarious interpersonal invasion that may jeopardize the future course of an interaction among peers. It can harmfully ostricize participants, disrupt or break a relationship, demoralize and cause emotional trauma.

On the other hand, it also offers a sense of concealed security to the parties involved, under the shared mental state of 'teasing'. This intersubjective state can also strengthen social ties and resolve or reduce conflicts; it can speed up the early stages of getting to know a new acquaintance; it can act as a means of demonstrating identity and distributing roles among a group, and can translate into a sense of proximity or affectional bonding between the parties involved, elevating communication between them at a psychosocially, emotionally, and cognitively more sophisticated level (Hendry, 2016; Boxer & Cortes-Conde, 1997). Hence, prosocial outcomes of teasing have also been identified and their value in the developmental process cannot be undermined.

By analogy, another form of intersubjective engagement which seems to carry connotations similar to those of teasing (and, by extension, bullying), is the act of tickling. When used prosocially, tickling serves as a source of enjoyment among peers which leads to shared laughter, enhances one's sense of self within a group, and creates affectionate bonds amongst the parties involved (Leavens & Bard, 2016). Nonetheless, even amongst children, there is a darker side to tickling, which is associated with displeasure, withdrawal and defensive movements (Harris & Alvarado, 2005).

Needless to say, when one uses tickling excessively, without tuning in to the recipient's state of being or their shared experience, any joyful quality is fast to diminish, and bullying (or even torture) is likely to ensue (Selden, 2004). However, when used as a benign deed between two children sharing a positive affective state, tickling, just like teasing, strengthens relationship bonds.

ENHANCING PSYCHOLOGICAL CONTACT IN SCHOOLS

Oftentimes teachers, principles, counsellors and parents are exempt from the shared intersubjective schema that is necessary to fully understand an interaction between children, trivializing displays of darker, or less amusing expressions of aggressiveness that may cause legitimate discomfort to the child who is on the receiving end. But even when they do intervene immediately, what is the best way to do so in order to put an end to the aggressive and marginalizing behavior? In other words, what are the best pedagogical solutions to prevent antisocial expressions of aggression or to intervene when the fun stops?

The existing paradigm restricts educators to roles that only allow for *defensive action*, such as assigning arbitrary intentions (i.e., harm to the bully) or flaws (i.e., weakness to the victim) and reiterating what constitutes harmful behaviour, in order to protect children from such experiences.

The view proposed in this chapter is based on an alternative assumption that invites school professionals to undertake preemptive roles in (i) creating constructive contexts and ground rules, (ii) maintaining the focus on the *process* instead of on the structure of the social exchange, and (iii) (whenever needed) reframing the meaning of potentially offensive practices by co-creating an objective world by means of intersubjectivity.

All three conditions are illustrated in the following testimony by the Danish existential philosopher Søren Kierkegaard.

“There is a form of envy of which I frequently have seen examples, in which an individual tries to obtain something by bullying. If, for instance, I enter a place where many are gathered, it often happens that one or another right away takes up arms against me by beginning to laugh; presumably he feels that he is being a tool of public opinion. But lo and behold, if I then make a casual remark to him, that same person becomes infinitely pliable and obliging. Essentially it shows that he regards me as something great, maybe even greater than I am: but if he can’t be admitted as a participant in my greatness, at least he will laugh at me. But as soon as he becomes a participant, as it were, he brags about my greatness.”

Here Kierkegaard (2000, p. 8) sums up the intersubjective aspects of bullying in public: the risks associated with the hostile and uninviting context of the exchange, the inherently aggressive process by which the parties interact, and the meaning of the outcome. Simultaneously, he resolves the ambiguity by using a casual remark to create psychological contact. This initiative essentially reframes the meaning of the exchange, which brings about a conflating sense of loyalty or bonding between two (or more) participants who have co-created an intersubjective state of teasing, where bullying once was.

Creating psychological contact with another person is the most crucial condition for successful relational interactions, yet we tend to assume its presence when it is not something that should necessarily be described as a logical non-sequitur (for more on the properties of psychological contact please refer to Prouty, 1998). In order to improve their capacity for being in contact with others and strengthen the child group cohesion, children need be presented with what Haslebo and Lunt (2015, p. 168) call a “relational way of thinking”; one that springs from relating critically to themselves and their situation and from reflecting on or imagining what another experiences, feels, thinks in order to identify, categorize, appreciate, and assess the behavioral consequences of their actions (Susswein & Racine, 2008). Such an approach seems to be particularly promising in the context of early childhood education, which is proactive, acknowledges each child’s experience, and builds resilience and respect from a young age.

ABSTRACT

Numerous research works are conducted about school bullying, cultivating emotional intelligence and digital story-telling. However, there is a lack of studies on the use of multimodal interactive media in raising awareness about bullying interactions in early stages among preschool children. In this study, an Interactive Storytelling scenario was designed and developed to detect the reactions of young children when facing bullying situations from the point of view of the child-victim. In this context, the prospects of the use of interactive digital storytelling as a means of enhancing social empathy in preschool children will be considered, given that relevant research in the preschool field is in its infancy.

Keywords: school bullying, interactive digital storytelling, anti-bullying strategies, empathy

INTRODUCTION

Bullying awareness is an important term in preschool education for the implementation of intervention and prevention practices (Goryl, Neilsen-Hewett & Sweller, 2013), since systematic bullying involves preschool groups and its origin lies in early childhood. Admission to kindergarten is a key developmental step, as children in this context participate for the first time as equal members of stable groups with common activities and are simultaneously exposed to examples of social acceptance and rejection. Rejection from the social group is the most common form of preschool bullying. Several studies have shown that peer rejection might be a risk factor which could lead to participation in bullying episodes (Crick & Grotpeter, 1996; Schuster, 1996; Boivin, Hymel & Bukowski, 1995).

Godleski, Kamper, Ostrov, Hart and Blakely-McCure (2014) found in their study that peer rejection increases relational victimization in early childhood and that emotion regulation skill predicts decreases in peer rejection and physical victimization. Bullying is a powerful risk factor in children's development, indicating that it is important to identify early symptoms to limit its development. Preschool age is the most effective time to help children acquire tools to manage bullying and develop positive strategies to confront it.

Bullying is mostly a phenomenon of social interaction (Reunamo et al., 2013) that unfolds within relationships, and therefore requires solutions that focus on the dynamics of these relationships. Children who are bullied find it hard to get out of a bullying relationship because they lack the strength to shift the dynamics of this relationship (Pepler et al., 2010). Bullied children themselves believe that the strategies they adopt to deal with the problem are most of the time ineffective (Tenenbaum et al., 2011). Therefore, studies on how to address the problem and the reasons why children choose to adopt a response strategy are needed (Hunter & Borg, 2006). By working on and evolving the active children's strategies, we create a tool with positive perspectives in bullying prevention.

The purpose of this study is to investigate and detect the strategies that preschool children adopt when involved in bullying situations and explore whether these strategies are associated with their individual characteristics and general social behaviors. Moreover, it intends to make them aware of the consequences of the phenomenon. This study uses the narrative power of the interactive digital storytelling to actively engage the children in a simulating condition of bullying, which they must *process* through the narrative choices of a branching story that corresponds to different categories of strategies, active or passive, as documented in the literature. There are three main processes in this interactive story: a) the "situation", the script bullying behaviors, b) the "reaction", the emergence of different options to address the situation that lead to different results in the continuum of bullying, adapting or impacting, linking the experiences gained from the story and c) the reactions of the characters to their own behaviors and reviewing their attitudes in a way that probably follows the story (Markouzis & Fessakis, 2016; Tsai, Tseng & Weng, 2011). This last process is completed by the oral narration of the story from the preschool students.

However, it is necessary to develop relevant scenarios for each possible protagonist role to experimentally examine the implementation of interactive digital storytelling in the prevention and addressing of bullying in preschool education. That is child-offender (bully), child-victim and bystanders with corresponding strategies for each leading role. In this article, it is presented the design of the first of the three interactive narrative scenarios projected, in which the main

character of the story has the role of the victim in the bullying incident. In this story, the main character is Anthoula, a five-year-old girl who is victimized due to rejection from the peer group. The script is a branching story structured with an interactive plot, and its final form will be combined with animation. It is pedagogically and developmentally appropriate for preschool children, as it utilizes narrative strategies that stimulate identification and narrative content that evokes intense feelings for the characters of the story, so that the children will interact with the characters and cultivate social skills and empathy. The results of this study will serve subsequently as a basis for assessing the use of interactive digital storytelling as a means of enhancing the social empathy of preschool children, as research on the use of interactive storytelling for bullying in preschool age is still in an early stage. The study is structured as follows: First, an introduction is made on the theoretical framework of bullying, followed by a brief description of the dimensions of empathy and how it relates to narrative and development of social skills. Second the use of interactive storytelling as the research tool of this project is described and, finally, the design of the proposed IST script on detecting anti-bullying strategies is presented.

THEORETICAL FRAMEWORK

The Concept of Bullying in Preschool Age

School bullying, defined as an “intentional aggressive behavior that is repeatedly carried out over time in an interpersonal relation characterized by an imbalance of power” (Olweus & Limber 1999), has been recognized as a serious and complex problem with negative and long-lasting consequences in the lives of the children involved in it. These psychological, social and academic consequences (Kaltiala-Heino, 2010; Rigby, 2008; Ttofi & Farrington, 2008; Hanish et al., 2004; Pereira et al, 2004) concern all children involved in bullying behaviors during their school life, whether they are victimizers, victims, victimizers-victims or observers (Swearer, Espelage & Napolitano, 2009) and, in extreme cases, can result in homicide or suicide (Wike & Fraser, 2009; Bauman & Del Rio, 2005).

According to Kirves and Sajaniemi (2012), 12.6% of preschool children (aged 3 to 6) were directly involved in bullying behavior (victimizers 7.1%, victims 3.3% and victimizers-victims 2.2%). Most of the research conducted to study school bullying focuses on middle childhood and adolescence, whereas there is little empirical evidence about the occurrence and the development of victimization in early childhood (Perren & Alsaker 2006; Hanish et al., 2004; Monks et al., 2002; Alsaker & Valkanover 2001; Kochenderfer & Ladd 1996; Alsaker 1993). Recent surveys indicate that bullying behavior is common in primary education (e.g., Kirves & Sajaniemi, 2012; Alsaker & Gutzwiller-Helfenfinger, 2010; Monks & Smith, 2010; Alsaker & Nägele, 2008), with aggression being more common among preschool children (aged three to five years) than any other age group (Hanish et al., 2004). In many countries, aggressive behaviors that resemble bullying and victimization by peers are observed in children at the age of 4 (Monks et al., 2005, 2002). Due to the lack of research, discussion on the definition of bullying among young children is limited and the definition used in research is mainly based on research on bullying among school-aged children (e.g., Alsaker & Gutzwiller-Helfenfinger, 2010; Alsaker & Nägele, 2008; Monks et al., 2005; Perren, 2000; Crick, Casas & Ku, 1999;

Kochenderfer & Ladd, 1996). Based on the above, bullying at preschool age is determined by the criteria of Olweus and his partners, i.e., the intention, repetitiveness and imbalance of power. As recognition of the phenomenon by young children rarely includes the above qualifying criteria (Vaillancourt et al., 2008), researchers that focus on preschool age questioned the strict use of the traditional definition of school bullying, by motivating the various researchers to examine and use the interpretations of young children as part of the definition used within the context of preschool education (Hamarus, 2006; Eriksson et al., 2002). Children, as social actors, can provide a unique view of their social world and the issues that concern them (Thornberg, 2008; James, 2007; Alanen, 2003; Prout, 2003).

Bullying is a subjective experience and it is important to consider the individual perspective of the situation for the definition, to prevent degradation of the children's bullying experience and their ability to self-protect, since children are able to detect bullying much faster than adults. In addition, they believe that this definition makes it difficult to distinguish between the initial appearance of more risky bullying behaviors in young children and their natural sequence in communicating aggressive behaviors (Hanish et al., 2004).

In general, bullying is a subset of aggression that can be categorized into three main types of behavior: indirect relational aggression, social rejection of the victim (Crick & Grotpeter, 1995) or "social aggression" (Smith, 2004; Smith et al., 2002), verbal (verbal violence) and physical (physical violence), as well as into two different types of functions, predominant and peripheral. Predominant functions are associated with the direct interactions of: preschool bullies, preschool victims and preschool bully-victims (Vlachou et al., 2013), whereas the peripheral functions are associated with the indirect interactions of assistants, reinforcers, defenders and outsiders (Vlachou et al., 2011). In their studies, Monks and Smith (2010) and Repo and Sajaniemi (2014) distinguished these roles even in ECE groups. Preschool assistants are those children who assist the bullies. Preschool reinforcers are those children who give the bully positive feedback. Preschool defenders are those children who support the victim. Preschool outsiders are those children who silently watch, nevertheless they encourage bullies.

BULLYING CONFRONTATION STRATEGIES USED BY CHILDREN

Depending on the children's role when involved in bullying and the emotional reaction that is linked with it, they either evolve bullying (leading to further victimization) or restrict it. The choice of focusing their reactions either externally on the same event, the bullying situation, or internally, in terms of emotional imprint, determines the effectiveness of bullying confrontation strategies. Confrontation strategies are categorized into active (such as problem solving), passive (such as ignorance) and aggressive (such as retaliation). Active confrontation strategies contribute to the prevention of aggression, while passive and aggressive strategies maintain aggression (Kochenderfer-Ladd & Pelletier, 2008; Wilton, Craig & Pepler, 2000). Confrontation strategies of victimized children are divided into those that focus on the problem (problem-focused) and those that focus on the emotion that causes the problem (emotion-focused). In the first case, children are actively involved in the search for confrontation strategies of the problem (e.g., *I tell the teacher, I defend myself*), while in the second case they do not try to change the problematic behavior. On the contrary, they avoid the situation (Skrzypiec et al., 2011; Tenenbaum et al., 2011; Hunter & Boyle, 2004).

According to Reunamo (2009), children's strategies can be found in the continuum of changing the child's own behavior (adapting) or changing the environment (impacting). Another continuum is considering the problematic situation (opening up) or applying the child's own ideas (assimilating) to the situation. Cross-tabulating these two continuums produces four possible strategies in problematic situations: accommodating (adapting and opening up), e.g., *Then he will tease me always.*, participating (opening up and agentive) e.g., *I tell the teacher*, dominant (agentive and assimilative) (e.g., *I hit him.*) and withdrawn (assimilative and adaptive) strategies (Reunamo, 2007).

Bullying among small children reflects the inability to cooperate in a child group. Most of the children coming to school, do not possess sufficiently the ability to manage conflicts, collaborate, share, play fairly and treat others with kindness. The processing of negative interaction with peers is an important developmental task that improves the social skills and relationships of children (Reunamo et al., 2013; Kokkinos & Kipritsi, 2012). This can prevent conflicts from becoming bullying over time. Without a valid and sensitive educational intervention, this impotence creates the risk that the child's behavior may eventually turn into bullying, so bullying prevention programs should be implemented in early childhood (Repo, 2015; Botsoglou & Andreou, 2013; Kirves & Sajaniemi 2012; Lee, Smith, & Monks, 2011; Vlachou et al., 2011; Monks & Smith, 2010; Alsaker & Nägele, 2008; Arsenea et al., 2006; Perren & Alsaker, 2006; Alsaker & Valkanover, 2001; Perren, 2000; Crick, Casas & Ku, 1999).

ANTI-BULLYING PREVENTION PROGRAMS FOR YOUNG CHILDREN

Increasing bullying rates led to a corresponding increase in educational anti-bullying prevention programs in schools (Tsai, Tseng & Weng, 2011; Swearer et al., 2010) and to teachers being more responsible, not only against bullying situations but also to connect pedagogical practices with anti-bullying strategies and awareness techniques (Olweus, 1993). However, many studies that examined the efficiency of several anti-bullying programs in schools (Flygare, Gill & Johansson, 2013; Beran, Tutty & Steinrath, 2004), reported mixed results. In a recent Swedish study of eight anti-bullying programs, the results showed little empirical evidence to support this goal (Flygare, Gill & Johansson, 2013). In a separate study examining research on anti-bullying initiatives, Swearer, Espelage, Vaillancourt and Hymel (2010) found that most anti-bullying school programs have little impact on reducing bullying-related behaviors.

The Finnish KiVa program and the Olweus Bullying Prevention Program (OBPP), are two of the most known complete intervention school programs. In the KiVa program, intervention consists of conversation with individuals or small groups that have been victims or participated in bullying incidents. These conversations are based on two different approaches: the method of shared concern (SC) (Pikas, 2002) and the disapproval of bullying method (DB). The SC method includes five discussion phases: in the first phase, a discussion with the bully takes place that aims to make the bully accept that bullying creates a problem to the victim, the second phase involves discussion with the victim, the third phase is a group meeting with the other members of the bully's team that probably affect his/her behavior, while the fourth phase consists of a meeting between the victim and the bully, who is committed to a contract with the aim of stopping the bullying practices. The last phase includes a feedback-evaluation of the results of the efforts made by the bully (Payne & Gottfredson, 2004).

According to a study conducted during the KiVa school program, both methods of discussion showed positive results in reducing the bullying behavior (Sainio et al., 2009). The Olweus Bullying Prevention Program (8-15 age) is based on four principles on how adults can deal with bullying in school: a) “showing warmth”, positive interest and involvement, b) setting firm limits to unacceptable behavior, c) the use of nonphysical and non-hostile negative consequences when rules are broken and d) the existence of authorities and positive role models (Olweus & Limber, 2010). It also underlines that the rules against bullying for each class should be an independent part of the school’s discipline policy (Olweus & Limber, 2017). Interventions of this program were implemented both on individual level as well as on school and class level, involving also parents and the community (Stamatis & Nikolaou, 2016; Smith, 2010).

Due to limited research on bullying among preschool children, interventions developed were mainly based on empirical assessments (Repo, 2015). The Bernese Program against Victimization in Kindergarten and Elementary School (Be-Prox), which was based on research for preschool environment, aims to familiarize teachers with bullying as a phenomenon and to educate them on prevention practices related to it (Alsaker & Nägele, 2008; Alsaker 2004; Alsaker & Valkanover 2012, 2001). The Be-Prox model has been included in an extensive study to evaluate anti-bullying programs and is among the nineteen most effective programs (Farrington & Ttofi, 2009). The National Association for the Education of Young Children (NAEYC) recommends two programs supported by numerous surveys: Steps to Respect: (8-10 ages) which focuses on relational types of aggression such as spiteful gossip and social segregation (Low et al., 2011), and Second Step (4-14 ages): which focuses on the development of emotional and social perspective skills, aggressive behavior management through discussion on acceptable social behaviors, modeling and role-playing (Snow, 2014).

As mentioned above, a common feature of intervention and prevention programs is the focus on the development of social skills and empathy (Nikolaou & Markogiannakis, 2017), that contribute to improving or strengthening positive interpersonal behaviors, based on the assumption that there is a causal relationship between low levels of empathy and bullying behaviors (Jolliffe & Farrington, 2011). Empathy facilitates the development of prosocial behavior (Warden & Mackinnon, 2003) and prevents or at least mitigates antisocial or aggressive behavior (Jolliffe & Farrington, 2006; Eisenberg & Miller, 1987). Empathy is an ability that can be modified by experience (Gerdes, Segal & Lietz, 2010; Davis, 1996) and storytelling, either digital or not, is included in these. Many research papers are following this direction in bibliography. The narrative approach, digital or not, is already beginning to appear in research on emotional intelligence and empathy enhancement (Faver & Alanis, 2012).

BULLYING STRATEGIES AND INTERACTIVE STORYTELLING

Theoreticians from various disciplines support the positive functions of reading stories-narrations, such as educational, moral development stories (Alexander, Miller & Hengst, 2001; Vitz, 1990) and stories that develop empathy (Mar & Oatley, 2008; Keen, 2007). A story can be defined as a series of phrases that describe a sequence of actions, events or experiences that are linked to cause-effect relationships and are usually related to people as agents of the story. People, who are depicted as characters in a story, are usually introduced in some typical human

situations in which – along with the factors and the changes that affect this situation from the outside environment – they react and change it. For Norris et al., (2005) a piece of prose is characterized as a narrative when it contains, to some extent, eight narrative elements: *narrator, reader, events, characters, time, structure, purpose and “narrative appetite”* (the desire created in readers and listeners to find out what will happen next).

Empathy can be defined as the act of perceiving, understanding, experiencing and responding to the emotional state of another person (Barker, 2003). Social empathy, according to Segal (2011), is “the ability to understand people by perceiving or experiencing their life situations, consequently gaining insight into structural inequalities and disparities”.

Davis (1996) considers empathy as a multidimensional construct that consists of four separate but related aspects: a) perspective taking (the tendency to spontaneously adopt the psychological point of view of others), b) fantasy (the tendency to transpose oneself imaginatively into the feelings and actions of fictitious characters in movies), c) empathetic concern (assesses “other-oriented” feelings of sympathy and concern for unfortunate others) and d) personal distress (measures “self-oriented” feelings of personal anxiety and unease interpersonal settings). The close relationship between empathy and prosocial behavior is well established (Eisenberg & Miller, 1987).

Story-telling is a powerful and authentic means in gaining a perspective on the conditions and feelings of others. Mar and Oatley (2008) point out that the main function of fictional narrative is to allow the reader to stimulate and learn from a deeply-felt fictional social experience. According to Mar and Oatley, when reading fiction, one feels real emotions, experiences and thoughts in response to the conflicts and relationships of the main story character. The component predicted by Mar and Oatley as being more influenced by narrative is affective empathy. Many narratives, fictional or not, include characters that present social behavior. According to social learning theory, the more a person simulates and learns from the characters that present social behavior, the more likely it is for the person to display prosocial behavior (Greitemeyer, Osswald & Brauer, 2010).

However, this narrative effect on prosocial development is not solely driven by the emotional empathy function but is mediated by the main character that symbolizes this function. This is supported by social learning theory as well as a recent study on the effect of modeled social behavior on emotional empathy, according to which the participation in video-games leads to empathic development, possibly because it activates game-related emotional variables (Greitemeyer et al., 2010). Moreover, the participation of the “visual image” as a narrative component becomes an inevitable part of the subject-object interaction during an experience. The power of the image, and especially the combination of image-movement (design), is no longer limited to the analogic theatrical framework but expanded and powered in the digital technological environment (television, video-games, etc.) (Diamantara, Fesakis & Varsamou, 2017).

INTERACTIVE DIGITAL STORYTELLING

Stories are an important cognitive schema which, in combination with the relevant mental processes (narrative intelligence), have been studied by psychologists, literary theorists and ICT scientists (Kolodner, 2005; Schank, 1995). Storytelling can be an excellent tool for

promoting emotional intelligence and social behavior on young children, which, combined with digital technologies, can be a powerful educational and highly reflective thinking activity (Sadik, 2008).

In addition, ICT enable the exploration of dynamic, non-linear stories structures, which are generally described as “interactive stories (IS)” and are also known as “interactive fiction” and “branching stories” (Crawford, 2013). Interactive stories enable the reader/player to participate and affect the plot of the story, offering new types of narrations, more engaging and adaptive. Conventional stories present a static sequence of events connected by an also static chain of cause-effect relationship (plot). In contrast, interactive stories present a dynamic sequence of events and a non-linear plot which is determined during the “reading” of the story according to the user’s actions and choices. The end of the story is not predetermined by the author and the story usually emerges during the narrative.

IST for educational purposes can support modern learning approaches, activate higher forms of thinking and emotional involvement during learning. In IST, the reader is “forced” to think about and understand the story, intervene to the simulated fictional world and make decisions for the narration evolvement. This mechanism activates the student-player’s thinking and concentration on the content and increases the possibilities of learning (Markouzis & Fessakis, 2017). The importance of storytelling in teaching and learning has been widely supported and is a widespread belief (Egan, 1993, 1985).

Considering that children enjoy and can understand stories from a very young age (Applebee, 1987), the interest on understanding and creating stories and using interactive digital storytelling as a means of encouraging social empathy and development of social behaviors in general, is quite reasonable. Despite the emerging pedagogical benefits, research on the role of interactive storytelling in bullying among preschool children is still in its infancy.

REVIEW OF ICT APPLICATIONS CONCERNING BULLYING

Examples of the available ICT applications about bullying, which, were studied prior to the preparation of this paper, are listed below on Table 1 in five categories. The study of existing ICT applications aimed to evaluating some selected or to informing about the process of the design of a new application. The lack of an appropriate application that matches to the theoretical framework analyzed before, led to the need of designing the scenarios described in the following section. In the rest of this section, the categories of the applications studied are described.

The first category is about animated or video branching stories that were developed in the framework of government initiatives in USA (Allen, & CPMMT, 2013; Risinger, 2011; Lenhardt 2007; National Crime Prevention Council, 1997). They can be used with young children of primary education, but they are not developmentally adapted to kindergarten (or younger children) and they lack empirical evidence.

The second category includes digital games created within the KiVa project (Yang & Salmivalli, 2015). These games appeal to older children or/and educators. Moreover, they do not have an intense narrative element with a complete plot. KiVa/Game 2 uses descriptions of short-term school incidents to ask questions but there is no continuity in the plot that depends on the answers.

Table 3. Categories of reviewed ICT applications concerning bullying

<i>Branching Stories from government initiatives:</i>
• McGruff animated dog interactive digital stories for bullying prevention. (http://www.mcgruff.org/Games/stop_bully.php). • “What happens next”, by Stop Bullying Organization, (https://www.stopbullying.gov/kids/games/play/).
<i>Digital games in the context of KiVa project (ages 7-10)</i>
• <i>Game 1</i> is a bullying awareness raising game. Its script structure is a closed-questions test for the identification of the phenomenon. • <i>Game 2</i> includes small episodes that are followed by a question to recognize the phenomenon. Game players’ age level corresponds to older children.
<i>Research efforts with Digital and Interactive Storytelling applications:</i>
• Tsai, M. K., Tseng, S. S., & Weng, J. F. (2011). A pilot study of interactive storytelling for bullying prevention education. <i>Edutainment Technologies. Educational Games and Virtual/Augmented Reality Applications</i>, 497-501. • Thompson, S. (2014). <i>Everybody's got a story: examining the building of empathy and understanding for the bully, the bullied, and the bystander through digital storytelling</i> (Doctoral dissertation, University of Ontario Institute of Technology (Canada).
<i>Branching animated stories for older children, adolescents and adults:</i>
• <i>Sir Basel Pike Public School</i> (http://www.zap.ca/pike). It is an interactive narrative role-playing game that explores the dynamics of bullying among boys and girls aged 10-14 (grades 5-9). The purpose of the game is to show what’s really going on in a couple of common schoolyard conflicts and to challenge the user to think about the consequences of impulsive action. The game presents a non-linear approach to problem solving that reveals to the user the cause and effect of different strategies of conflict resolution. The central idea is to develop empathy through victimization. • <i>Decisions that matter</i> (http://www.etc.cmu.edu/projects/patronus/). It is an interactive stimulation game about bystander intervention. It is both a video game and a powerful lesson in how you can protect yourself and your friends from sexual assault. Developed by Carnegie Mellon University students (Yoo, 2015).
<i>Digital Games for empathy development:</i>
There are many digital games on empathy development and emotional intelligence in general (Greitemeyer, Osswald & Brauer, 2010). e.g., http://www.pbs.org/pov/thankyouforplaying/empathy-video-games/

The third category includes published research on the implementation of digital storytelling for bullying, in which, however, the script is not interactive (Thompson, 2014) or it is left to be invented and digitized by the children (Tsai, Tseng & Weng, 2011) and thus it cannot be easily applied in preschool education. However, choosing the application of digital and interactive storytelling to combat bullying, strengthens the approach proposed in this study.

In the fourth category are included two professional-level animated branching story applications aimed at raising awareness and tackling bullying and aggressive behavior in adolescents and students. Although these projects are not intended for preschool age or have experimental documentation, they are indicative of the dynamics of the media and are a model for our approach.

Finally, in the fifth category are digital games about social interaction stimulations for enhancing empathy and emotional intelligence of children (Greitemeyer, Osswald & Brauer,

2010). We believe that this is the general category of the media in which we incorporate the proposed interactive story that specializes in bullying and preschool age.

By reviewing the existing applications, it is ascertained that there is generally a lack of interactive storytelling applications about bullying for preschool children designed with theoretical analysis and documented by systematic research on their effects and outcomes.

Moreover, it is noted that social interactions stimulations are theoretically able to affect the emotional intelligence of children through the situated learning theory. Situated knowledge is the idea that knowledge can only be objective when paired with a perspective that makes it true. Empathy games help with gaining situated knowledge because they expose users to situations that they would not normally experience. With the right perspective, the user can now understand the validity of statements they would otherwise question because they had not been exposed to that perspective. Video games teach perspective-taking skills by obligingly changing the player's perspective, as the player is placed in stage and this causes a short-term "explosion" of sympathy, which is not enough to truly understand the situation of other children, but it can help change the player's perspective on the situation. Batson and colleagues suggested that perceived need, imagining the other's perspective, and valuing the other's welfare are antecedents of empathy (Batson et al., 2007). The differentiating element in the development of positive prosocial behaviors through narratives (textual, visual, acoustic) is related to: a) the empathic dimension that is activated by them, either cognitive (playing the game as a main character) or emotional (playing the game as a separate person that has the same feelings as the characters) and b) the amount of involvement in the plot of the story, through the process of identifying with the main character. Green and Brock (2000) posit that transportation into a story occurs when an individual is fully engaged, experiences high imagery, and is emotionally impacted by the story.

Considering the theoretical analysis described above, designing digital interactive storytelling scenarios especially for preschool children to investigate their effect on bullying, seems to have a significant interest.

PROPOSED INTERACTIVE BULLYING SCENARIO

In this study, it is considered that the cognitive components integrated as narrative options in an interactive scenario (e.g., "What do you think Anthoula should do? (1st Branch: 1a) Make her painting again? Or 1b) Hide behind the dollhouse?) with a content that causes emotions, will enhance cognitive and emotional involvement of preschool children in their interactions with the main character of the story (Anthoula), as they will be forced to make decisions for the narrative to develop. That participation in the narrative development makes the child an active agent of the story, enhancing thus identification (Appleyard, 1994). Increased identification leads: a) to a greater amount of empathy (the child may feel not just "some" feelings towards the character but "those" feelings the character experiences) and b) to inclusion in the story, i.e., minimization of the difference between what the child understands as happening in the story and what happens between the child and the story, when there is a positive response to the story. By asking "What did you like the most?" or "What made you the biggest impression?" In the end of the interactive story, we examine the child's positive or negative emotions towards the story or one of the characters are examined, since success or

failure to adapt to the story is revealed by the feedback the child receives by evoking feelings (Holland, 1968).

According to Holland's Psychoanalytic Theory, a positive response to the narrative outlines that the child managed to compose, from elements found in the story, a part or all his/her lifestyle, a part or the entire structure of his/her defenses (Holland, 1975) and as a result, this positive response will help the child to make those narrative choices that will more consistently reflect his/her strategies if he/she was bullied at that time (limiting the possibility of choosing randomly or indifferently a branching choice-strategy). Given the above difficulties, "Anthoula's Dreams" was created, a digital interactive story featuring a five-year-old girl, named Anthoula, who receives social rejection from her classmates. Social rejection and teasing in kindergarten are the most common forms of bullying. Children-players are required to choose from predefined options of strategies, those that will lead to the resolution of the bullying situation and reconciliation, aiming to learning positive strategies of resolution. The narrative was created by considering "The 5 essential elements" (Ohler, 2001), thus achieving emotional flow between the actions of the characters and the narrative events of the story.

Figure 2. Script excerpt from twine showing the branching structure.

Moreover, when exposed to the negative choices of the strategies and the possibility of reduced self-awareness, the child's feelings are protected, since the script's structure allows children a) to see themselves as actors, not just victims, and b) the "corrective experience". This means that if the child feels anxious from the negative route that he/she chose, it can return to the previous crossroad and choose the positive route that will lead this time to an active resolution of the problem. In addition, as research has shown (Reunamo et al., 2013), children's strategies reflect their activities. The branching scenario was specified using the Twine Interactive Fiction authoring tool (Figure 1 & 2). The scenario is currently available only in Greek language and it may be translated in other languages depending on the results of the pilot study of its impact. An animation movie prototype is under development to illustrate the story of the scenario using the Animaker software (Figure 3). The animated video clips will be embedded in a custom story exploration software through which the users will interact with the story and make their decisions. The software will track the decisions of each specific user. The

impact and the efficiency of the proposed application of the interactive storytelling will be thoroughly studied as soon as the animated versions are complete.

Children who adopt uncertain strategies concentrate on non-social activities and do not have as many experiences of social interaction with other children. These children may find it difficult to interact in a constructive way and may not have social interaction skills. At the end of the story, we answer the questions of five "W": Who? What? Where? Why? When? (Black, 2017), to enhance children's visualization capability, regarding the projected message of our story (basic problem-solving skills). Visualizing the facts and events of the story, makes the actions of the characters meaningful, as they are formulated through narrative, while permitting the identification and favoring the listener's participation in the narrative events. Thus, the proposed scenario is a good condition for simulating social experience and skills for these children (Ong, 1982).

Figure 3. The Twine's users' interface.

Figure 4. Screenshot from the animation created with Animaker software.

CONCLUSION

Raising awareness is an important term in preschool education for implementation of intervention and prevention practices (Goryl, Neilsen-Hewett & Sweller, 2013), since systematic bullying includes preschool groups, as children's interactions lack of developed social skills. The interactive nature of the phenomenon dictates the development of social skills due to the causal relationship between low levels of empathy and bullying behavior (Jolliffe & Farrington, 2011). Empathy, as a cognitive and emotional ability which can change with experience (Gerdes, Segal & Lietz, 2010; Davis, 1996), makes the narrative a highly formative experience that, in combination with digital technologies, constitutes a strong educational and highly reflective thinking activity (Sadik, 2008).

The result can be made even more complete by combining the interactivity of multimedia applications and the positive “responsiveness” of the child-agent to the narrative spectacle, which now works in a convincing and plausible way, as the children's narrative choices through the story branches are expected to more consistently reflect their own strategies, if they were intimidated at that time. Based on this reasoning and given that children enjoy and can understand a lot of stories from very young ages (Applebee, 1987), two additional digitized interactive scenarios will be created along with the existing story with interactive structure (“Anthoula Alone”), focusing on the roles of the child-perpetrator and children-bystanders respectively, both for the diagnosis and assessment of the children's reactions to bullying situations as well as for the effect of interactive stories on the development of strategies for addressing bullying.

ABSTRACT

Bullying is a crucial social problem for youth in all countries and cultures, yet few cross-country studies of bullying have taken into account cultural differences in bullying, particularly how it is conceptualization and operationalized. We demonstrate how differences in conceptualization, operationalization and measurement lead to inconsistent findings that affect implications for prevention and intervention. This investigation may help to further cross-national bullying studies by providing clear recommendations that will help researchers to take account of culturally appropriate comparisons. To compare the same concept (i.e., bullying) across countries, it is beneficial to have a unified conceptualization and operationalization of bullying that also reflects cultural differences. In turn, this can guide the implementation of effective prevention and intervention programs that are culturally, developmentally, and gender appropriate.

Keywords: bullying, South Korea, youth, cross-country study, literature review

INTRODUCTION

Since the 1970s, bullying in childhood and adolescence has been understood as a serious and ongoing problem that has negative consequences for perpetrators, victims, and bystanders. Along with diverse negative consequences, substantial research has examined and compared bullying across countries (Chester et al., 2015; Due et al., 2005). These studies have identified

* Corresponding Author's Email: dalhee.yoon@case.edu.

the tendency of bullying and illustrated its harmful effects on youth development, as well as to demonstrate the potential for continuing adverse consequences throughout the lifespan (National Academies of Sciences, Engineering, and Medicine [NASEM], 2016). However, the cross-national bullying studies have limitations that did not take account for conceptualization, operationalization, and cultural differences. These differences make it difficult to compare findings across studies that utilize samples of youth from different cultures and countries.

Therefore, we illustrate these challenges and differences of international bullying studies to suggest how to prepare for future cross-national bullying studies in culturally sensitive ways, using the potential significance of cultural variances in the concept of bullying. To identify similarities and differences among international studies, we used South Korean bullying studies by comparing this work to some of the most well-known studies of bullying in English speaking youth. The reasons South Korean research has used to explain the challenges of international bullying comparison studies is that research on bullying in South Korea has grown steadily since the early 2000s and has important implications for research in other international comparison studies. Additionally, bullying in South Korea has not yet included, although several previous research has compared bullying across diverse countries (Chester et al., 2015; Craig et al., 2009; Elgar et al., 2015; Wilson, Dunlavy, & Berchtold, 2013). This research may be applicable to other countries' studies and may expand our understanding of the current problems in cross-national bullying studies. It can also help to guide future international comparison bullying studies, which may now more clearly account for specific cultural differences and similarities across countries.

Conceptualization Differences across Countries

One of the biggest challenges of understanding findings of cross-national studies of bullying is differences in how bullying is conceptualized defined. The different conceptualization of bullying contributes to different findings, and it further leads to the implementation of different prevention and intervention programs. According to Flannery et al., (2016) and the NASEM report in 2016, the problem of varied definition of bullying across studies has been identified even within English-speaking cultures. However, international studies of bullying have not been examined to determine whether they also conceptualize bullying in different ways. If these inconsistencies exist, it will contribute to a lack of comparability of findings across studies and potentially miscommunication among researchers, practitioners, and policy makers. For example, if policies and laws are based on inconsistent findings or data that is not based on a consistent definition of the problem, then decisions on funding and preventive intervention strategies may be misguided and ultimately ineffective.

Most studies including both South Korea research and English-speaking cultures, utilize the concept of bullying developed by Olweus' in his Scandinavian studies. Olweus (1978) introduced "bullying" as a research concept nearly 40 years ago and his studies remain at the center of research on bullying today. According to Olweus's definition (1994), bullying refers to intentional aggressive behavior that is persistent and repetitive toward an individual or a group and is characterized by an imbalance of power. Although most English-speaking cultures adapted Olweus's concept, the Centers for Disease Control and Prevention (CDC) officially developed a uniform definition of bullying in 2014. According to the CDC (2015), bullying is defined as "any unwanted aggressive behavior(s) by another youth or group of youths who are

not siblings or current dating partners that involves an observed or perceived power imbalance and is repeated multiple times or is highly likely to be repeated” (p. 1). The CDC’s definition distinguishes bullying from peer victimization. *Peer victimization* refers to harassment by one or more age-mates that can happen once and without a power differential between perpetrator and victim, which distinguish it from bullying (Finkelhor, Turner, & Hamby, 2012). For example, if a child is hit by a peer in a single incident, and there is no power differential between the two, then this case is technically peer victimization instead of bullying. Some researchers use the two terms interchangeably, while others assert that these are distinctly different phenomena (NASEM, 2016).

Similar with English-speaking cultures, South Korean bullying research also used the Olweus conceptualization of bullying, a situation with an individual harassed persistently and repeatedly by a group or an individual due to an imbalance of power—regardless of geographical placements (such as school, bus-stop, playground, etc.). The primary difference in conceptualization between South Korea and English-speaking cultures is the unit of the perpetrator. If an individual is harassed by an individual, this does not constitute bullying according to South Korea’s definition, but it does in English-speaking cultures. Bullying research in South Korea has used mixed terms, even though an official term for bullying, “Jib-Dan-Tta-Dol-Lim,” has emerged. Given the origin of this term (i.e., “Jib-Dan” means “group” in South Korea), the bullying perpetrator must be a group, not an individual, whereas the perpetrator could be either a group or an individual in English-speaking cultures. This differentiation of definition has produced a varied range of bullying prevalence in previous studies: in the US, studies of bullying indicate that between 13% and 75% of children and adolescents are bullied at some point in their lives (Gladden et al., 2014), while the prevalence of bullying victimization in South Korea ranges from 24% to 56% (Hu, Park, & Jung, 2009). In short, the different conceptual definition (i.e., unit of the perpetrator) affects methods of assessing bullying rates, which in turn are related to variance in the estimation of bullying rates. These inconsistencies hinder our ability to understand the prevalence and impact of bullying, and they limit our ability to develop effective prevention and intervention programs.

Operationalization Differences across Countries

In addition to conceptual definition issues with regard to bullying, there are issues with how bullying as a concept is operationalized. Although both South Korea and English-speaking cultures utilized the Olweus’s concept of bullying, subsequent studies have operationalized and measured bullying in many different ways, making comparisons of findings difficult and implications for prevention and intervention hard to determine. In English-speaking culture, diverse assessments have been utilized ranging from observations of behavior (e.g., unstructured and structured observations, interviews), a single question (e.g., have you been bullied), and different questionnaires such as the Bullying Behavior Scale (BBS; Austin & Joseph 1996), the Peer Nomination Inventory (PNI; Wiggins & Winder, 1961), the Peer Relations Questionnaire (PRQ; Rigby, 1998), the Peer Victimization Scale (PVS; Neary & Joseph, 1994), and Olweus’s Bully/Victim Questionnaire (BVQ; Olweus, 1996) in order to measure bullying. Although these diverse assessments provide information about different aspects of bullying, each has limitations in providing information about bullying according to the CDC definition. For instance, the BBS was developed to measure bully-victim problems at

school including two six-item self-report scales, which have higher levels of internal consistency (Austine & Joseph, 1996; Crothers & Levinson, 2004). However, the BBS items fail to assess the imbalance of power and the number of repeated occurrences. Additionally, the BBS restricts the physical locations of bullying by limiting its focus to school property.

Olweus's BVQ also has limitations because it excludes power imbalance and the number of repeated incidents of bullying (Lee & Cornell, 2010). The gap between the instrument (i.e., BVQ) and the recently adopted definition of bullying is especially problematic because these instruments are widely used in bullying studies across countries as a standardized and validated questionnaire (Kyriakides, Kaloyirou, & Lindsay, 2006; Lee & Cornell, 2010). By excluding the repeated nature of bullying and imbalance of power, an incident could be interpreted as school violence or peer victimization instead of bullying. These methodological issues are consistently reported in previous research (Nansel et al., 2001; Solberg & Olweus, 2003; Ttofi & Farrington, 2011). In effect, each study has established its own definition of bullying. This variation in definition may be even more pronounced in international comparison studies because of cultural differences and translation issues. However, to date, most bullying studies have been focused on Canada or the U.S., and few studies have pointed out the operational definition problems of bullying studies across countries (Bradshaw, 2015).

Compared to English-speaking cultures, South Korean studies uniquely and clearly categorize three types of bullying: 1) social exclusion; 2) verbal harassment; and 3) physical molestation. These types can be further divided into visible and invisible bullying (Lee & Kwak, 2000). Visible bullying refers to people around the victim recognizing the bullying through observing physical or verbal harassment, while invisible bullying is social exclusion such as ignoring, teasing, or being shunned. Although studies in English-speaking cultures use similar categories of bullying, these studies have not yet clearly defined the types of bullying.

Questionnaires in South Korea also more clearly categorize roles in bullying—perpetrator and victim—while questionnaires in English-speaking cultures focus almost exclusively on victimization. These differences have been identified in the national datasets. For example, the School Crime Supplement (SCS) is a national survey targeting youths aged 12-18 in the U.S. for bullying and cyber-bullying based on the CDC's definition (U.S. Department of Education, 2015). The SCS has diverse information related to the characteristics of students, but it only focuses on the person being bullied without considering the perpetrator or bystander. However, as a representative national longitudinal dataset in South Korea (Kwon, 2011; No & Hong, 2013), the South Korean Youth Panel Survey (KYPS) contains 5-year longitudinal data from 4th grade of elementary school (approximately ages 9-10) to the 2nd grade of middle school (approximately ages 13-14). In the datasets, perpetration and victimization of bullying are measured through the history of events (i.e., presence or absence of bullying) and the frequency of events. In sum, most of the national datasets in English-speaking cultures are focused only on the victim of bullying, whereas the national datasets in South Korea include studies that assess the experiences of both victims and perpetrators. However, both countries did not consider the bystander.

Additionally, there are distinct differences in South Korean questionnaires, because of translation issues. For example, questionnaires in several Korean bullying studies have used Callaghan and Joseph's (1996) peer victimization scale and Neary and Joseph's (1994) bullying-behavior scale, as translated by Lee and Kwak (2000). However, a few items on the questionnaire do not precisely translate from the original questionnaires or their response categories. These differences may cause researchers to measure constructs differently. For

example, Lee and Kwak's translated questionnaire (2000) includes swear words as a type of verbal harassment, but Callaghan and Joseph's questionnaire includes only teasing, name-calling, etc. as verbal harassment types.

South Korean questionnaires can be categorized into three types: 1) those developed by researchers; 2) those adopted from other South Korean language questionnaires; and 3) those translated into Korean from other languages. First, questionnaires that have been developed by researchers are designed for each researcher's purpose and tailored to their target behaviors. For example, Jang and Choi (2010) developed a questionnaire to measure bullying in South Korea by creating four subscales through factor analysis: retaliating, assisting bullies, bystanding, and helping victims. The four subscales were to measure these attitudes towards bullying. Second, adopted questionnaires have mixed the concepts of bullying and peer violence. For example, Lee (2003) developed a peer violence questionnaire in her study of the relationship between peer violence and general life experience. However, Kim and Yook's study (2014) used Lee's peer violence questionnaire to measure bullying because the items on the questionnaire included bullying concepts. Third, Baek (2015a, 2015b) translated the peer victimization scale and bullying behavior scale, which were developed by Austin and Joseph (1996). In her study, the peer victimization scale was used to assess bullying victimization, whereas the bullying behavior scale was utilized to assess bullying perpetration.

Each type of measurement has strengths and limitations. The questionnaire developed by researchers has strengths given the nature of a study that develops its scale in order to tap the identified construct. For example, Kim's study (2003) developed a scale that examines the conformity groups for bullying. In her study, the conformity group is categorized into active and passive support groups. The active support group is also divided into two groups based on the subject of support: support perpetrators or victims. In short, Kim's study has established a measurement to assess bystander patterns, because of the limited assessments for bystanders. However, using a uniquely developed measurement makes it difficult to generalize to other samples and to compare findings across studies and cultures.

Adopted South Korean language questionnaires also have the strengths of being convenient and of reflecting South Korean cultures. Although there is limited information on how each study measures the concepts, several limitations were identified in previous research. Major limitations include difficulties in matching the target population, in addition to reliability and validity issues. Park and Kim (2015), Moon et al., (2013), and Kwon et al., (2012) used the same bullying victimization scale developed by Jang and Choi (2010). However, these studies' target populations are different ranging from elementary school students to middle school students. Given the different target populations, these studies' reliabilities vary widely: respondents' levels of literacy and cognitive ability are related to the reliability and validity issues (DeVillis, 2012). Therefore, it is problematic to use the same scale for a wide range of age samples. This limitation is a problem not only in South Korea, but also in English-speaking cultures. Bradshaw's study (2015) demonstrated, for example, that study results in the U.S. differ depending on the reporter (i.e., self-report vs. teacher- or peer-report).

Lastly, a translated study has strengths by utilizing standardized assessment, such as Olweus's BVQ. However, these studies have translation and cultural issues. For example, Eom and Cho's study (2015) used a Korean version of Olweus's BVQ, which excludes harassment due to race or ethnicity. These translation issues have led researchers to produce different constructs.

Despite the important differences between South Korea and English-speaking cultures described above, there are nonetheless several similarities in the operationalization of bullying as a construct. In general, most types of bullying harassment have been divided in three ways—physical, emotional, and verbal—in both countries’ questionnaires. These shared categorizations demonstrate both cultures’ commitment to understanding the underlying compositions of bullying. Additionally, most assessments in both South Korea and English-speaking cultures, which often adopt (or, in Korea’s case, translate) existing questionnaires, have gaps between construct and measurement. In contrast, the questionnaires developed by researchers have fewer such gaps by developing the assessment with clear purpose.

Intervention Approach Differences across Countries

Consistent with previous studies (Hong, Lee, Lee, Lee, & Garbarino, 2014), prevention and intervention programs have taken different approaches due to different concepts and cultural differences: South Korea is more likely to prefer the selective- or indicated-level programs, whereas English-speaking cultures are more likely to suggest universal-level school-based prevention programs. This may be explained by the underlying different emphases on the subject (victim or perpetrator) of the bullying as well as cultural differences. In the Korean perspective, since bullying is group-based harassment, bullying victimization results from the individual’s social-interactive problems, which may provoke the bullying group. However, in English-speaking cultures’ perspective, bullying can take the form of individual or group harassment, which leads researchers to consider environmental problems. Over the last two decades in English-speaking cultures, diverse bullying prevention and intervention programs have increased to meet the demands of the times, which consider bullying to be a significant social problem. Most of these interventions—especially for at-risk youth already involved in bullying—address constructs and behaviors related to bullying such as aggression, violence, and externalizing behavior problems. However, they rarely target bullying behaviors specifically (Flannery et al., 2016; NASEM, 2016).

For example, school-based “Social and Emotional Learning (SEL)” programs, as a universal approach, target all students regardless of risk for bullying and foster youth-positive development frameworks including cognitive, affective, and behavioral competencies in order to reduce negative adjustment such as interpersonal violence, substance use, and bullying (Durlak, Weissberg, Dymnicki, Taylor, & Schellinger, 2011). Along with SEL programs, diverse school-based programs that adopt a universal approach have been examined in previous studies, which revealed the effectiveness of school-based programs using meta-analytic review. These studies found that bullying perpetration and victimization were decreased 17-23% (Jimenez-Barbero, Ruiz-Hernandez, Llor-Zaragoza, Perez-Garcia, Llor-Esteban, 2016; Ttofi & Farrington, 2011). One such selective program is “Method of Shared Concern,” which seeks to help individuals and groups to resolve bully/victim problems by working with practitioners. This intervention was originally developed by Anatol Pikas in 2002, and it has been evaluated as an effective program having positive outcomes (Rigby & Griffiths, 2011), even though the evaluation used a small number of cases. As for indicated bullying programs, one example is the “Target Bullying Intervention Program (T-BIP)”’: a three-hour individualized intervention for students who have engaged in bullying as a perpetrator to reduce their aggressive behaviors

by identifying cognitive and environmental factors related to bullying (Strawhun, Fluke, & Peterson, 2013).

In regards to the level of intervention program, most research on bullying programs in South Korea has focused on indicated- and selective-level programs (Byeon, 2000; Kong & Bae, 2013). Among the studies discussed in this review, only Seo and colleagues (2011) and Kim (2013) have examined universal level programs including school-wide social skills training programs and counseling programs for peer support at elementary schools. This focus on selective or indicated programs is different than in studies from English-speaking cultures, even though there have been limited RCT studies in South Korea. While limited to only South Korean programs, Hong and colleagues' study (2014) also identified similar results in their review of bullying and school-violence prevention and interventions; most Korean bullying prevention and intervention programs are individual-level and target specific individual behaviors. Although Hong and colleagues' review (2014) included studies of bullying and school violence, nonetheless they still considered primarily selective or indicated programs, not universal interventions. This discrepancy reflects the gap between Korean and Anglophone cultures' perspectives on bullying: The Korean perspective on bullying tends to focus on individual problems, whereas the perspective of English-speaking cultures is more likely to focus on environmental problems. It also suggests that English-speaking cultures' studies of bullying in other cultures (e.g., South Korea) need to better take into account cultural differences in conceptualizations of the definition of bullying.

One of the other characteristics of programs in South Korea is target populations; victims have been the main targets in prevention and intervention programs (Chung, Chung, Kim, & Park, 2008; Kim, Lee, & Kim, 2008; Kwon & Kim, 2006; Son & Hong, 2009). Oh's literature review (2010) examined the limitations of current prevention and interventions for bullying in South Korea and revealed the overall ineffectiveness of intervention for the perpetrator. Additionally, Oh has advocated for developing preventive interventions based on the characteristics of Korean bullying (i.e., group-based bullying). In contrast, interventions in English-speaking cultures have targeted diverse populations including victims, perpetrators, and bystanders (NASEM, 2016).

DISCUSSION

The current study examined the similarities and differences between South Korea and English-speaking cultures in order to address the problems of comparing bullying research across studies and countries. This study has important cautionary implications not only for future international comparison studies of bullying, but also for comparing such studies within countries by identifying the variances in study results due to different conceptual and operational definitions, as well as cultural differences. Numerous differences between the literature on bullying in Korean and in English-speaking cultures have been indicated. First, the concept of bullying in South Korea differs from English-speaking cultures: the Korean concept has been focused on group-based bullying, whereas English-speaking cultures consider either individual-level bullying or group-based bullying. Additionally, compared to English-speaking cultures, the Korean literature categorizes bullying more clearly into the following roles: perpetrator and victim. These different conceptual definitions affect how researchers

measure bullying, which in turn leads to a diverse range of findings (i.e., different ranges of prevalence, creating different focus on national datasets, and distinct intervention strategies). Our findings thus indicate that English-speaking cultures should consider developing clearer categorizations of bullying based on the distinct characteristics of victims, perpetrators and bystanders described in previous studies (Espelage & Holt, 2013; Hymel & Swearer, 2015; Nansel et al., 2001; Yen et al., 2014).

Although several differences have been identified in studies in South Korea and English speaking countries, there are also considerable similarities. First, the initial step in research in South Korea was to study Scandinavian bullying research, which had a notable influence on the development of questionnaires. Bullying questionnaires, regardless of what country the research is being conducted in, usually categorized bullying as physical, emotional, or verbal. Most assessments also perpetuate the mismatch between the concept of bullying and how it is operationalized in research studies, because most assessments adopt existing questionnaires rather than developing their own. These mismatched concept and operationalization problems have been more likely to be found in South Korean questionnaires, compared to English-speaking cultures, given the nature of translation issues that do not account for cultural differences. In other words, the translated questionnaires are more biased, even though most translated questionnaires use the standardized scale.

Suggestions for Future Research

The identified similarities and differentiations have implications for future research. First of all, the findings suggest that researchers should develop a clear and matched definition with operationalization, because the gap between construct and operationalization hinders our ability to determine the effectiveness of prevention and intervention programs. For example, interventions developed according to a different concept may not effectively reduce bullying. This gap between concept and operationalization should be considered not only across international comparison studies, but also within cultures, because we identified the variation in results both within countries (Nansel et al., 2001; Solberg & Olweus, 2003; Ttofi & Farrington, 2011) and across countries (Baek, 2015a; Baek, 2015b; Bradshaw, 2015; Kim & Yook, 2014). Second, future studies that examine bullying across countries should consider cultural differences. Such differences have caused widespread repercussions because South Korea and English-speaking cultures fail to examine the same construct. For example, if researchers use the term “bullying” without further explanation, people who have different cultural backgrounds may interpret different concepts, which in turn will lead to divergent responses. Additionally, cultural differences make different school climates. For example, school cultures in South Korea are collectivist, whereas English-speaking cultures are more individualistic. As a result, students in South Korean schools are more likely to be afraid of speaking or acting out, and may be bullied by other peers if they do. Ironically, South Korea’s collectivist attitudes lead to far more targeted interventions (because bullying victims and perpetrators are seen as acting outside of the larger group), while for example American individualist attitudes result in a preference for more universal interventions.

These cultural differences are the pivotal problem, specifically in the U.S., given its more multicultural population. Thus, researchers in the U.S. should take account of these cultural differences when they conduct bullying research by using culturally appropriate questionnaires.

For example, a culturally matched interviewee and interviewer would be helpful in order to understand the targeted construct (i.e., bullying), when researchers collect bullying data. This matched interview may lead to high fidelity. Additionally, few studies have examined the prevalence of bystanders, even though bystanders are understood to play a significant role in the social dynamics of bullying (Espelage & Holt, 2013; Hymel & Swearer, 2015; Kim, 2003; Nansel et al., 2001; Noh, 2000; Yen et al., 2014). Therefore, future studies should consider the prevalence of bystanders as well as the unique problems of bullying in vulnerable populations.

Chapter 37

GENDER DIFFERENCES IN BULLYING AND SUICIDE

Jane Timmons-Mitchell, PhD and Seungjong Cho[†]*

Case Western Reserve University, Cleveland, OH, US

ABSTRACT

Introduction: This chapter reviews the relationship between bullying and suicide with special attention to types of bullying and gender differences.

Bullying: Both Boys and Girls are Targets of Bullying at Similar Rates; Boys are More Likely to Bully, and Girls are More Likely to Report.

The 2016 National Academies report summarized bullying statistics in the US: “school-based bullying likely affects between 18 and 31 percent of children and youth, and the prevalence of cyber victimization ranges from 7 to 15 percent of youth.” (National Academies of Sciences, Engineering, and Medicine 2016, p. 2)

Suicide: More Females than Males Think about Suicide but More Males than Females Die by Suicide.

Suicide has increased 28% since 2000; it was the 10th leading cause of death for people of all ages in 2015 in the US. Among 15-24 year olds, suicide is the second leading cause of death. According to Youth Risk Behavior Survey data, 17.2% of students had seriously considered suicide in 2017. Suicide ideation and suicide attempts were higher among female (22.1% and 9.3% respectively) than male high school students (11.9% and 5.1% respectively).

Bullying and Suicide: Being a Target of Bullying, and Especially Engaging in Bullying Behavior, Elevates Suicide Risk Whether You Are a Girl or a Boy.

The relationship between suicide-related behaviors and bullying (victim, perpetrator, bully-victim, or bystanders) has been established. Students who were bullied, bullied other students, or witnessed bullying were more likely to have higher levels of suicide-related behaviors than students not involved in bullying. There is evidence that female and male students experience the effects of bullying differently and engage in suicide attempts at different rates. Girls who are bullied and girls who are bully-victims have higher involvement with suicide. The National Violent Death Reporting System (NVDRS) data

* Corresponding Author's Email: jct2@case.edu.

[†] Corresponding Email: seungjong.cho@case.edu.

supports that there is a relationship between bullying and suicide. From 2005-2008, 12.4% of NVDRS suicide records for 10-17 year olds from 16 states referenced bullying.

Method: We examined the studies in the Holt and colleagues (2015) meta-analysis individually, cataloguing the prevalence of bullying experiences and suicide related behavior reported, focusing on gender, bullying, and suicide. We then located articles published after the Holt meta-analysis was conducted. Taken together, these studies described bullying experiences, suicide ideation and attempts worldwide; gender was factored in. The results from over 400, 000 students in 45 countries were summarized.

We obtained and analyzed Ohio's NVDRS data from Ohio Department of Health for 2010-2016. A total of 26 bullying-related cases (10-17 years old) were identified between 2010 and 2016. Most (22) were deaths by suicide. Of these, most (65.4%, $n = 17$) were male.

Conclusion: While there is not a 1:1 correspondence between bullying and suicide, there does appear to be a relationship. Understanding how bullying impacts female and male youth differently, and how this relates to suicidal intent as well as to death by suicide is an area for further inquiry. It is important not to overlook boys who are involved in bullying and possible suicidal ideation. This is especially true among boys with minority sexual orientation.

1. INTRODUCTION

This chapter reviews recent empirical studies and international reports on the relationship between bullying and suicide with special attention to types of bullying and gender differences. We discuss two major sources of data regarding gender, bullying and suicide:

- 1) Studies that connect the variables among living students; and
- 2) Data reporting on young people who have died using the NVDRS (National Violent Death Reporting System).

1.1. Bullying: Both Boys and Girls are Targets of Bullying at Similar Rates; Boys Are More Likely to Bully, and Girls Are More Likely to Report

Bullying is "repeated, intentional, harmful and aggressive behavior inflicted by a person or group with more power on a person or group with lesser power" according to Nansel et al. (2001). In the 2005-2006 academic year, US students reported prevalence rates of 21% for physical bullying, 54% for verbal bullying, 51% for social bullying and 14% for electronic bullying (Wang, Iannelli and Nansel 2009).

In the 2013 Youth Risk Behavior Survey (YRBS; Centers for Disease Control and Prevention 2014), 19.6% of high school youth (US) indicated that they had been bullied on school property in the 12 months before the survey. The difference between female and male youth is striking: 23.8% of girls and 15.6% of boys reported being bullied at school. In the same survey, 8.7% of girls and 5.4% of boys said that they did not go to school because they felt unsafe at school or on their way to or from school. Twenty one percent of girls and 8.5% of boys reported being electronically bullied. According to the most recent YRBS in 2017, 19.0% of high school students reported being bullied at school (Kann et al. 2018).

The National Academies of Science, Engineering, and Medicine (2016) summarized the range of bullying statistics: “school-based bullying likely affects between 18 and 31 percent of children and youth, and the prevalence of cyber victimization ranges from 7 to 15 percent of youth” (p. 2).

UNESCO (2018) published a compendium on *School Violence and Bullying: Global Status and Trends, Drivers and Consequences*. Using a variety of large-scale data techniques, the report details prevalence of different types of bullying among 9-15 year olds in 144 countries and territories worldwide. Overall, the report concludes that about one in three students (32%) was bullied by peers at school within the last month. Overall, girls and boys are equally likely to experience bullying. Gender results reveal that more boys than girls are involved in physical fights (45.4% vs. 25.4%). Girls are more likely to be bullied based on physical appearance. Gender non-conforming students are more likely to be bullied than their heterosexual peers (34.2% vs. 18.8%).

1.2. Suicide: More Females than Males Think about Suicide But More Males than Females Die by Suicide

Suicide has increased 28% since 2000 and it was the 10th leading cause of death for people of all ages in 2015 (Curtin, Warner and Hedegaard 2016), accounting for 44,965 deaths in the US (National Center for Health Statistics 2018). In 2016, 13.42 deaths were recorded per 100,000 habitants (American Foundation for Suicide Prevention 2018; CDC 2018). Among older teenagers and youth, suicide is the second leading cause of death; in 15-24 year olds, suicide accounts for 13.2% of deaths in 2016 (National Center for Health Statistics 2018). The CDC (2017) reports that, in 2015, suicide deaths for teenage girls ages 15 to 19 were the highest they have been since 1975. Suicidal ideation and suicide attempts are frequent in adolescents; lifetime prevalence of attempt peaks between 16 and 18 years of age (Gould et al. 2003).

According to YRBS data, 17.2% of students had seriously considered suicide in 2017 (Kann et al. 2018). The prevalence of suicide ideation was higher among female (22.1%) than male high school students (11.9%) while that of suicide attempts was 9.3% vs. 5.1%. Global suicide trends for youth show that females are more likely to consider suicide while males are more likely to die by suicide.

In the UNESCO report, health outcomes, including seriously considering suicide are affected by bullying. About twice as many bullied students (23.4%) compared with 12% of non-bullied students reported suicidal thoughts. Gender breakdown for bullying and suicide is not reported.

1.3. Bullying and Suicide: Being a Target of Bullying, and Especially Engaging in Bullying Behavior, Elevates Suicide Risk

The relationship between suicide-related behaviors and bullying (victim, perpetrator, bully-victim, or bystanders) has been established by existing studies (e.g., Borowsky et al. 2013; Espelage and Holt 2013). Students who were bullied, bullied other students, or witnessed bullying were more likely to have higher levels of suicide-related behaviors than students not involved in bullying (CDC 2014). There is evidence that female and male students experience

the effects of bullying differently and engage in suicide attempts at different rates (Nansel et al. 2001).

The National Violent Death Reporting System (NVDRS) data supports that there is a relationship between bullying and suicide. Karch et al. (2013) found 12.4% of NVDRS suicide records, 2005-2008, for 10-17 year olds from 16 states referenced bullying. Created in 2002, the NVDRS is a state-based surveillance data system collecting information on all violent deaths including suicide. The restricted-use data is currently available from 40 states, the District of Columbia and Puerto Rico.

2. METHOD

In the present chapter, we examine the studies contributing to the Holt and colleagues (2015) meta-analysis individually, cataloguing the prevalence of bullying experiences and suicide related behavior reported, focusing on gender. Forty-two studies were based on administration of questionnaires in schools. Five studies involved settings other than schools (two were administered at mental health clinics and three included participants from other settings); these are excluded from our discussion. We then located articles published after the Holt meta-analysis was conducted. Taken together, these studies describe bullying experiences, suicide ideation and attempts worldwide; gender is factored in. Populations covering all ages of students in 45 countries totaling over 400, 000 participants are summarized.

We also obtained and analyzed Ohio's NVDRS (OH-VDRS) restricted-use data from the Ohio Department of Health for 2010-2016.

3. RESULTS

3.1. Review of Studies

We reviewed 42 of the 47 studies include in the Holt et al. (2015) meta-analysis, removing the studies that concerned samples not drawn from schools. Both bullying perpetration and victimization were more common among boys than girls with a few exceptions. Suicide ideation and suicide attempts were typically higher among girls than boys. The relationship between bullying and suicidal behaviors was generally consistent regardless of gender. A significant association between bullying victimization (either as a victim or a bully-victim) and suicidal ideation was consistently identified. Some studies showed that the relationship between bullying victimization and suicidal ideation can be stronger for girls than for boys. Frequently, previous studies used a single measure of bullying and suicidal behaviors, usually a question or two such as those on the YRBS, which could be a methodological limitation. In the Holt et al. (2015) report, gender was defined as studies with an all-female sample, all-male sample, or mixture sample, but a "mixture sample" is not further defined. If the contrast variable was based on the all-female or all-male studies, the number is very small and may have related to the lack of finding. Country of origin, which was also included as a potential moderator, did show a result for bullying perpetration and suicidal behavior. US based studies showed a large effect size for country of origin: being both a bully and a victim, and suicidal behavior (OR, 10.22;

95% CI, 9.04–11.56) relative to non-US-based studies (OR, 2.36; 95%). Gender, using the definition, did not show an effect.

The 12 Studies published after the Holt et al. (2015) review tend to be larger and longitudinal in nature. For example, in a systematic review by Klomek, Sourander and Elonheimo (2015), bullying by peers in childhood (ages 5-16 years) affected suicidality in adulthood (ages 18 years and older). This review included large-scale longitudinal studies worldwide between 1960 and early 2015. Studies included were (a) the Finnish 1981 Birth Cohort Study, (b) the Great Smoky Mountains Study, (c) the British National Child Development Study, and (d) the Avon Longitudinal Study of Parents and Children. Gender differences of the effects of bullying were a focus of the review. Girls showed a significant association between childhood bullying victimization and later suicidal behavior. Girls were also less likely to be bully perpetrators than boys, but those who were bully perpetrators tended to have a higher risk of suicidality in adulthood.

3.2. OH-VDRS Data Analysis

This study described the circumstances of suicide among youth and young adults aged 10-24 in Ohio. According to CDC WISQARS, suicide rates of this population were 8.69 (per 100,000 individuals), which were higher than the national average of 10-24 years (8.42 per 100,000). The current study analyzed Ohio Violent Death Reporting System (OH-VDRS) from 2010 to 2016. Suicide in Ohio for 10-24 year olds has held steady and in 2016, and the proportion of suicides has decreased to 46.3% of overall deaths from 52.3% in 2010. Demographic, suicide specific, and circumstance information were analyzed for the suicide-only data ($N = 1,415$).

3.2.1. Demographic Information

Figures 1 through 4 depict the demographic information of the OH-VDRS suicide-only data. In sum, 79.2% were male and 20.8% were female. 84.2% were white and 13.9% were African Americans. 95.9% were non-Hispanic.

Figure 1. Gender of OH-VDRS (suicide-only).

Figure 2. Age group of OH-VDRS (suicide-only).

Figure 3. Race of OH-VDRS (suicide-only).

Figure 4. Ethnicity of OH-VDRS (suicide-only).

3.2.2. Suicide Specific Information

Figure 5 depicts the suicide methods of the OH-VDRS suicide-only data. 44.6% ($n = 631$) died by hanging, strangulation, or other suffocation, while 43.6% ($n = 617$) died by gunshot. 5.0% ($n = 71$) died by drug intoxication. 5.7% ($n = 80$) died by other causes (e.g., fall, crash, drowning, stab, etc.), and 1.1% ($n = 16$) of cases did not report this information. In addition, 16.8% had a history of attempting suicide prior to the injury, and 22.9% disclosed their suicidal intent to another person. 33.0% left a suicide note (written note or social media post, etc.).

Note that there is a significant difference in drug intoxication deaths between 2010 and 2016 (chi-square = 32.304, $p = .020$). The proportions of suicide by drug intoxication were 8.2% in 2010 and 4.5% in 2016.

Figure 5. Suicide methods of OH-VDRS (suicide-only).

3.2.3. Circumstance Information

- Most suicide incidents took place at house (74.4%, $n = 1,053$), and 59.6% ($n = 844$) of cases were injured in their own home.
- A total of 1,157 cases (81.8%) involved EMS at the scene, and 350 cases (24.7%) visited the emergency department.
- A total of 295 cases (20.8%) of cases were diagnosed with depressed mood at the time of injury.
- Relationship problems
 - 20.2% ($n = 286$) of cases had an argument or conflict that was reported to have led to their death.
 - 30.5% ($n = 431$) had problems with their current or former intimate partner, contributing to their death, and 14.0% ($n = 198$) of cases coded this intimate partner issue as a “crisis.”
 - 11.4% ($n = 162$) had family relationship problems (other than intimate partner), and 2.9% ($n = 41$) of cases coded this family relationship issue as a “crisis.”

Table 1. Studies on bullying and suicide by gender, Holt et al. (2015)

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Baldry and Winkel, 2003	High school students ($M = 16.0$; $Range = 14\text{--}19$ years) in Italy $N = 998$	Victimization scale by Olweus (1993) measuring (a) direct victimization and (b) relational victimization	Suicidal cognition (suicide thoughts + suicide attempts): Child Behavioral Check List scale for ages 11–18	Female reported more frequent suicidal thoughts than male. Suicidal cognition was associated with gender and age: older girls were more at risk of suicidal cognition than boys.	
Bauman, Toomey and Walker, 2013	High school students in US (14–17 years; Arizona Youth Risk Behavior Survey [YRBS] 2009) $N = 1,491$	Measures from YRBS 2009 (5 questions asking traditional school bullying, cyberbullying as victim or perpetrator) Victim: traditional victimization and cyber victimization Perpetrator: traditional bullying and cyberbullying	Suicide measures from YRBS 2009 (three questions asking suicide thoughts, suicide plan, and suicide attempts)	Female reported more suicide thoughts, suicide plan, and suicide attempts than male. Traditional victimization was significantly associated with suicide attempts only for girls. Cyberbullying was significantly associated with suicide attempts only for boys.	
Bonanno and Hymel, 2010	High school students ($M = 14.2$; 13–15 years) in Canada $N = 399$	32-item bullying questionnaire developed by authors asking involvement in bullying as a bully, victim, or witness	Suicidal Ideation Questionnaire–JR scale by Reynolds (1987) asking suicidal ideation	No result on gender differences A significant association between victimization and suicidal ideation was identified.	
Bonanno and Hymel, 2013	High school students ($M = 14.2$; 13–15 years) in Canada $N = 399$	Modified 10-item measure originally developed by Olweus (1993) asking traditional (physical, verbal, and social) and cyber bullying	Suicidal Ideation Questionnaire–JR scale by Reynolds (1987) asking suicidal ideation	Female students reported more suicidal ideation than male students. Male students reported more physical victimization, verbal victimization, physical bullying, and verbal bullying than female students.	Verbal and cyber victimization and verbal and cyber bullying were significantly associated with suicidal ideation.
Borowsky, Taliaferro and McMorris, 2013	6th, 9th, 12th graders (11–17; Minnesota Student Survey 2010) in US $N = 130,908$	Two questions asking verbal/social bullying perpetration and victimization	Two questions asking suicide ideation and suicide attempt	Girls were significantly more likely to report suicidal ideation and suicide attempt than boys.	
Cheng et al., 2010	Middle school students in China (12–16 years; Global School-based Health Survey; GSHS) $N = 9,015$	Two questions asking being bullied measuring frequency and forms of bullying	Two questions asking suicide ideation and suicide planning	Rates of being bullied were similar for males (27.4%) and females (23.8%). Physically being bullied were higher for male students, while psychologically being bullied were higher for females.	Students who had recently considered suicide were more likely to report being bullied.

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Coggan et al., 2003	Secondary school students (12–18 years) in New Zealand <i>N</i> = 3,265	Asking chronic bullying during the past 6 months and its form (verbal teasing, racist comments, physical violence, and sexual harassment)	Two dichotomous measures of suicide ideation and suicide attempts	Girls were more likely to have suicidal ideation and suicide attempts, and have been bullied than boys. Being victimized by bullying were associated with suicide ideation and attempts.	27% of the students had experienced chronic bullying during the past 6 months. 11% had attempted suicide.
Cui et al., 2010	Middle school students (12–16 years) in China (GSHS 2003) <i>N</i> = 8,778	A question asking frequency of being bullied	Two dichotomous measures of suicide ideation and suicide attempts	Rates of being bullied were similar for males (29.7%) and females (27.2%). Girls were more likely to report both suicide ideation and attempts than boys. The association between being bullied and suicide ideation/attempt was stronger for girls than for boys.	
Delfabbro et al., 2006	Students (<i>M</i> = 15.2; 14–16 years) of secondary school in Australia <i>N</i> = 1,284	Five questions asking bullying/victimization experiences by peers and teachers at school and outside of school	8-item scale developed by authors asking suicidal ideation, suicide planning, and suicide attempt (summed to measure levels of suicidal ideation)	Boys were more likely to be bullied than girls both at school and outside of school. At both rural and urban public schools boys reported more victimization experiences than girls. Girls scored higher on suicidal ideation than boys.	Victimization by teachers: Boys were more likely to be picked on by teachers than girls, especially in the metropolitan area.
Espelage and Holt, 2013	Middle school students (10–13 years) in rural area in US <i>N</i> = 661	18-item University of Illinois Aggression Scale having three factors: bullying (9-item), fighting (5-item), and victimization (4-item)	Two items from the Youth Self-report asking suicidal ideation and history of self-injury	Female bully-victims particularly elevated suicidal ideation and attempt. Overall, 60% of bully-victims, 43% of physical bullies, and 32%–38% of victims and verbal bullies reported suicidal ideation compared with 12% of uninvolved youth.	44% of bully-victims, 35% of physical bullies, and 24%–28% of victims and verbal bullies reported history of self-injury (8% of uninvolved youth).
Fisher et al., 2012	Twin children (age 12) in UK (Environmental Risk study) <i>N</i> = 2,141	Frequency of bullying experiences assessed by children's mothers when the children were 7 and 10 years old, and by children's self-report when they reached 12 years old	Self-harm experiences assessed by children's mothers when the children aged 12 years	More than half of children who had self-harmed were victims of frequent bullying. Frequent bullying experience before age 12 predicted higher self-harm rates at 12 years of age. This association was similar to boys and girls.	
Fleming and Jacobsen, 2009a	Middle school students (<i>M</i> = 13.7; 13–15 years) in Chile (GSHS 2004) <i>N</i> = 8,131	Two questions asking bullying victimization: one for frequency and the other for type of victimization	Two binary questions (yes/no) asking suicide thoughts and suicide planning	Boys were more likely than girls to report being bullied, but girls were more likely than boys to report suicidal thoughts.	46.6% students reported having been bullied in the past month (mostly verbal bullying).

Table 1. (Continued)

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Fleming and Jacobsen, 2009b	Middle school students (12–16 years) in 19 countries (All available GSHS between 2003 and 2006)	A question asking frequency of peer victimization during the past 30 days	A question asking suicide thoughts (yes/no)	Boys were more likely than girls to report being bullied. Students who reported being bullied were more likely to report suicidal ideation than non-bullied students.	The prevalence of bullying was lower with increasing age.
Gower and Borowsky, 2013	6th, 9th, 12th graders (11–17); Minnesota Student Survey 2010) in US <i>N</i> = 128,681	A question asking the frequency of bully perpetration and another question asking the frequency of bully victimization	Suicide measures from YRBS 2009 (three questions asking suicide thoughts, suicide plan, and suicide attempts)	Gender moderated association between victimization and suicidal ideation. Infrequent victims were at higher risk of suicidal ideation compared to never-victimized students, and this was particularly true for girls.	Students engaging in infrequent bullying (both perpetration and victimization) had increased levels of self-harm than students without bullying involvement.
Hay and Meldrum, 2010	Students (<i>M</i> = 15.0; 10–21 years) in a rural county in US <i>N</i> = 426	Traditional bullying victimization scale measuring physical and verbal bullying (6-item) Cyber bullying victimization scale(3-item)	A question asking frequency of suicidal ideation Another question asking frequency of self-harm (purposely hurt without wanting to die)	Significant and positive relationships between traditional/cyber bullying and suicidal ideation/self-harm. Girls had higher self-harm than boys. No gender difference in suicidal ideation.	
Heilbron and Pristein, 2010	Middle school students (<i>M</i> = 12.6; 11–14 years) in an urban county in US <i>N</i> = 493	Peer nomination measure: Asked to identify peers who were targets of the (a) overt and (b) relational victimization	Repeated measures (three time points) of suicidal ideation and nonsuicidal self-injury (NSSI)	A latent growth curve analysis revealed that high levels of overt victimization were related to high levels of suicidal ideation over time for girls.	Relational victimization did not predict either concurrent or longitudinal suicidal ideation for both sexes.
Henry et al., 2014	6th–12th grade students (11–17 years) in a urban school district in US <i>N</i> = 2,936	Measures of bullying victimization and perpetration (relational, physical, threats, and cyber bullying) by the Multisite Violence Prevention Project 2004	4-item scale measuring the frequency of suicidal ideation during the past week	Boys tended to report more bullying experiences and girls tended to report higher suicidal ideation.	
Hepburn et al., 2012	High school students (14–17 years) in Boston <i>N</i> = 1,838	5-item measure asking bullying victimization 2-item measure asking bullying perpetration	A question asking suicidal ideation and another question asking suicide attempt	Compared to students who did not involve in bullying, perpetrators, victims, and bully-victims were more likely to report suicidal ideation and suicide attempt. No gender difference identified.	Bully-victims were at highest risk for both suicidal ideation and suicide attempt.
Herba et al., 2008	Children (<i>M</i> = 12.3 years) in Netherlands	Peer nomination (presented with a list of classmates to rate them into (a)	Two-item measure of suicide ideation from the Youth Self-Report	Compared to children uninvolved in bullying, those rated as bully-victims or	

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
	$N = 1,526$	bullying (by whom are you bullied?) and (b) victimization (whom do you bully?)	(YSR; Achenback, 1991): (a) I deliberately try to hurt or kill myself. (b) I think about killing myself.	victims did not report higher levels of suicide ideation (no association). No gender difference in suicide ideation.	
Hinduja and Patchin, 2010	Middle school students ($M = 12.8$; 10–16 years) in US $N = 1,963$	Measures of (a) traditional bullying victimization, (b) traditional bullying offending, (c) cyberbullying victimization, and (d) cyberbullying offending	4-item measure of suicidal ideation adapted from the American School Health Association's (1989) National Adolescent Student Health Survey	No gender difference in suicidal ideation (girls: 19.7%, boys: 20.9%). Both traditional and cyber bullying (either as a victim or a bully) experiences were associated with more suicidal thoughts and suicide attempt.	Victimization was more strongly associated with suicidal thoughts and suicide attempt than perpetrating.
Holt et al., 2013	Primary and secondary school students (8–16 years) in Singapore $N = 3,096$	Three measures of traditional (5-item), cyber (5-item), and mobile phone (2-item) bullying victimization	One question asking suicidal ideation due to bullying (Have you ever thought of killing yourself because you were bullied?)	Girls were more likely to report suicidal ideation. All three types of bullying victimization were associated with suicidal ideation. Notably, 27.8% of students experienced mobile phone bullying reported suicidal ideation.	The relationship between mobile bullying and suicidal ideation was significantly stronger for boys than girls.
Ivarsson et al., 2005	Students ($M = 14.0$; 13–16 years) in Sweden $N = 183$	Two questions asking frequency of bullying victimization and perpetration	Two questions asking suicidal ideation and suicide attempt	Boys were more likely to be bully only and girls were more likely to be victim only.	Victim only and bully-victims reported higher suicidal ideation than bully only.
Kaltiala-Heino et al., 1999	Secondary school students (14–16 years) in Finland $N = 16,410$	Two questions asking involvement in bullying either as a bully or as a victim adapted from an European study by World Health Organization (King et al. 1996)	Two items in the Back Depression Inventory (BDI) asking suicidal ideation ("having definite plans about committing suicide" & "killing myself if I had the chance")	Boys (9%) showed higher prevalence of bullying involvement as bully than girls (2%; as victim: 6% vs. 5%). No gender difference in prevalence of severe suicidal ideation (both 2%). Higher prevalence of severe suicidal ideation was reported among both bully and victim students.	Prevalence of suicidal ideation was highest among bully students.
Kim et al., 2009	Middle school students (13–14 years) in South Korea $N = 1,655$	28-item Korean-Peer Nomination Inventory (K-PNI) asking to name classmates who fit the description in each item (11 items for victim, 6 items for bully, and 11 neutral items)	At baseline, two items asking suicidal ideation and suicide attempt in the past 6 months. At 6-month follow-up, one additional item asking suicidal ideation in the past 2 weeks with the two items above	Girls reported more suicidal ideation and suicide attempt than boys. Female persistent bullies (involved in bullying both time points) showed increased risks for suicidal attempt at follow-up. Male newly involved bullies at follow-up showed increased risk for suicidal ideation over last 2 weeks.	For both girls and boys, bully-victims showed increased risk for suicidal ideation than uninvolved youths.

Table 1. (Continued)

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Klomek et al., 2009	Children born in 1981 in Finland (cohort study) <i>N</i> = 5,302	Assessed at age 8 from children, parents, and teachers asking frequency of bullying victimization and perpetration	Assessed at age 25 to measure suicide attempts and completed suicides from Cause of Death Registry, Hospital Discharge Register, and death certificates	Boys who were frequent victims and frequent bullies were more likely to be suicidal than boys who were not involved. Girls who were frequent victims were more likely to be suicidal than girls who were not victims.	56.2% of boys bullied other kids and 24.2% of girls bullied. 57.2% of boys were bullied and 39.8% of girls were bullied.
Kowalski and Limber, 2013	Students (<i>M</i> = 15.2; 11–19 years) in rural area in US <i>N</i> = 931	Measures of traditional bullying (2 items from Olweus Bullying Questionnaire) and cyberbullying (2 items)	One item from Beck Youth Depression Scale (BDI-Y) asking suicidal ideation	A significant interaction of gender and traditional bullying was obtained on suicidal ideation.	No significant association between traditional/cyber bullying and suicidal ideation.
Laukkanen et al., 2005 ^a	Psychiatric clinics outpatients in Finland (<i>M</i> = 17.7; 11–22 years) <i>N</i> = 168	Two binary measures asking bullying victimization and perpetration at school	An item in BDI scale asking suicidal ideation	Suicidal ideation in boys associated with being bullied at school. Suicidal ideation was higher for those who were bully-victims.	64% of study participants reported suicidal ideation.
LeVasseur, Kelvin and Grosskopf, 2013	High school students in US (14–17 years; New York City YRBS 2009) <i>N</i> = 11,488	A measure asking the frequency of bullying victimization during the past 12 months	A measure asking the frequency of suicide attempts during the past 12 months	Girls reported higher suicide attempts than boys. 11.2% of students reported bullying victimization and 9.9% reported suicide attempts. Students who were bullied had higher odds of suicide attempt than those not bullied.	Sexual minority youths had higher odds of attempting suicide and reporting bullying. The effect of bullying on suicide attempt was strongest among non-Hispanic sexual minority boys.
Liang, Flisher and Lombard, 2007	8th and 11th graders (13–18 years) in South Africa <i>N</i> = 5,074	Two binary measures asking bullying victimization and perpetration at school during the past 12 months	Two questions asking suicidal ideation and suicide attempt	Boys reported higher perpetration and victimization than girls. Bully-victims showed higher rates of suicidal behaviors than either bully or victim groups.	36% of students were involved in bullying behavior (8% as bullies, 19% as victims, and 9% as bully-victims).
Litwiller and Brausch, 2013	High school students (<i>M</i> = 16.1; 14–19 years) in rural area in US	Items from YRBS measuring the frequency of physical bullying (3-item) and cyberbullying (3-item) during the past 30 days e.g., How many times has someone	Four binary items from YRBS measuring suicidal ideation, suicide planning, self-injury and suicide attempt during the past 12 months e.g., Did you	No result on gender differences 33 % reported being a victim of physical bullying, 23 % reported being a victim of cyberbullying, and 30 % reported	Both physical bullying and cyberbullying associated with suicidal behavior.

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
	N = 4,693	threatened or injured you with a weapon, such as gun, knife, or club on school property? Has anyone sent you a threatening or aggressive e-mail, instant message, or text message?	ever seriously consider attempting suicide? Did you make a plan about how you would attempt suicide? How many times did you actually attempt suicide?	suicidal behavior (a combined subscale having all the four suicide measures).	
Luukkonen et al., 2009 ^a	Adolescents (12–17 years) in Psychiatric inpatient care in Finland N = 508	Bullying behavior measure using Schedule for Affective Disorder and Schizophrenia for School-Age Children Present and Lifetime (K-SADS-PL)	Suicide attempts measure using K-SADS-PL (When performed at least one suicide attempt with definite suicidal intent or when it was life-threatening)	13% of boys and 26% of girls had attempted suicide. There was a higher risk of suicide attempts who were victims or bullies only for girls. A significant difference in bullying behavior and suicide attempts between genders.	29% of boys and 38% of girls were victims, 20% (boys), 10% (girls) were bullies, and 7% (boys), 5% (girls) were bully-victims.
Mark et al., 2013	Students (15–16 years) in Estonia, Lithuania, and Luxembourg N = 4,954	Two binary measures asking bullying victimization and perpetration during last two months	A binary measure asking suicidal ideation in the past 12 months	Proportions of suicidal ideation were higher among girls (16.8–25.1%) across the 3 countries than boys (10.9–14.6%). Boys reported more bullying perpetration than girls (no gender difference of bullying victimization).	Overall, 17% of students had suicidal ideation and 16% of students had been bullied.
Mills et al., 2004	Students (M = 14.1; 12–15 years) in Ireland N = 209	An item in K-SADS-PL measuring a history of bullying victimization	Scale for Suicide Ideation (SSI; 19-item) for all and Suicide Intent Scale (SIS; 19-item) only for students had attempted suicide	No result on gender differences Bullying victimization was significantly associated with suicidal ideation and suicide attempt.	35% of students had been bullied.
Park et al., 2006	Students (15–17 years) in South Korea N = 1,312	A binary measure asking bullying victimization	A binary measure asking suicidal ideation during the past 2 weeks	Girls were more likely than boys to have experiences suicidal ideation. Bullying victimization was associated with suicidal ideation for both sexes.	12% of girls and 7% of boys reported suicidal ideation in the past 2 weeks.
Patrick et al., 2013	8th, 10th, 12th graders (13–17 years) in Washington State, US N = 27,752	A measure asking bullying victimization because of perceived sexual orientation (PSO)	A binary measure asking suicidal ideation during the past 12 months	9–14% of boys and 6–11% of girls reported being bullied because of PSO. 22–29% of PSO-related bullied boys and 38–45% of PSO-related bullied girls reported suicidal ideation.	Being bullied because of PSO was associated with increased suicidal ideation.

Table 1. (Continued)

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Pranjić and Bajraktarević, 2010	Students (age 17) in Bosnia & Herzegovina <i>N</i> = 290	Peer nomination measure: Asked to identify peers who were victims, bully-victims, and uninvolved	An item in BDI scale asking suicidal ideation	Higher prevalence of suicidal ideation was identified for both victims and bully-victims than uninvolved. No gender difference of bullying.	
Rigby and Slee, 1999 – Study 1	Students (<i>M</i> = 14.9; 12–18 years) in Australia <i>N</i> = 1,103	Self-report measures of bullying perpetration (6-item) and victimization (5-item)	4 items from Goldberg Health questionnaire asking suicidal ideation during the past few weeks	Boys reported higher bullying perpetration and victimization than girls. No gender difference was found for suicidal ideation.	
Rigby and Slee, 1999 – Study 2	Students (<i>M</i> = 14.0; 12–16 years) in Australia <i>N</i> = 845	Peer nomination measure of bullying perpetration and victimization (asked to choose the same gender as themselves)	4 items from Goldberg Health questionnaire asking suicidal ideation during the past few weeks	Boys reported higher bullying involvement and girls reported higher suicidal ideation. Involvement in bullying at school was related to suicidal ideation, especially for students with relatively lower perceived social support.	
Rivers and Noret, 2013	Secondary school students (<i>M</i> = 13.6; 12–16 years) in UK <i>N</i> = 1,592	15-item anti-bullying measure asking bullying involvement (uninvolved, victim, bully, bully-victim, observer), bullying types, bullying reasons, based on the Olweus Bully/Victim Questionnaire	An item from Brief Symptom Inventory (BSI) to measure suicidal ideation	Girls reported more bullying perpetration and victimization than boys. For boys, bullying perpetration was significantly associated with suicidal ideation. For girls, either bullying perpetration and victimization were not associated with suicidal ideation.	Those not involved in bullying were less likely to report suicidal ideation compared to bullying observers.
Roland, 2002	8th graders (age 14) in Norway <i>N</i> = 2,088	Two measures (4 items each) asking the frequency of bullying victimization and perpetration during the current school year	A measure asking suicidal ideation (4-point Likert scale)	Girls reported higher suicidal ideation and boys reported higher bullying involvement. Bullying perpetration and victimization were associated with suicidal ideation.	Only for girls, bullies had higher suicidal ideation than victims.
Romero et al., 2013	Latina students (14–18 years) in Arizona <i>N</i> = 650	4 items from Arizona YRBS 2009 measuring bullying victimization and perpetration during the past 12 months	Suicide measures from YRBS 2009 (three questions asking suicide thoughts, suicide plan, and suicide attempts)	No result on gender differences (girls-only study) Bullies were 1.5 times higher suicidal ideation and 1.4 times higher suicide planning than non-bullies.	Victims were 1.5 times more likely to attempt suicide than non-victims.

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Schneider et al., 2012	High school students (14–17 years) in Boston <i>N</i> = 20,406	Cyberbullying victimization and school bullying victimization in the past 12 months adapted from YRBS	Two binary measures of suicidal ideation and suicide attempts in the past 12 months	Reports of cyberbullying were higher among girls (18.3%) than boys (13.2%). Reports of school bullying were similar for both genders (25.1% for girls & 26.6% for boys). Victims of both cyber and school bullying were more likely to report suicidal ideation and suicide attempt than non-victims, cyberbullying only, and school bullying only.	15.8% students reported cyber bullying and 25.9% reported school bullying in the past 12 months. 60% of cyber bullying victims were also school bullying victims.
Skapinakis et al., 2011	High school students (16–18 years) in Greece <i>N</i> = 2,431	2 items measuring bullying victimization and perpetration in the last 2 months by the revised Olweus Bully/Victim questionnaire	An item measuring suicidal ideation in the past week by the revised Clinical Interview Schedule (CIS-R)	Bullying perpetration was not associated with suicidal ideation. Bullying victimization was associated with suicidal ideation. These associations were similar in both boys and girls.	This association was particularly strong for those bullied on a weekly basis.
Turner et al., 2013	Middle and high school students (<i>M</i> = 13.8; 11–17 years) in North Carolina <i>N</i> = 1,874	6-item scale measuring physical, verbal, and cyber bullying experiences in school	Two-item scale measuring the frequency of suicide ideation during the past 12 months (a combined measure of suicide ideation and suicide planning)	Any type of victimization was associated with higher levels of suicide ideation for females and males. No gender differences in suicide ideation identified.	
Undheim, 2013	Students (12–15 years) in Norway <i>N</i> = 2,464 (cohort study)	Assessed at age 14 to measure bullying victimization (3-item) and aggression toward others (4-item)	Assessed at age 15 to measure both active and passive suicidal ideation (4-item)	Among the subgroup being bullied, girls had higher levels of suicidal ideation than boys. Being bullied at age 14 was related to higher suicidal ideation at age 15.	Being aggressive toward others was related to suicidal ideation.
van der Wal, de Wit and Hirasings, 2003	Children (9–13 years) in Netherlands <i>N</i> = 4,721	Direct and indirect forms of bullying victimization and perpetration using the Amsterdam Children's Bullying questionnaire	Two binary questions asking suicidal ideation	Suicidal ideation was more common among children who were sometimes or frequently being bullied directly. Direct bullying had a significant effect on suicidal ideation only for girls.	Suicidal ideation was common in bullies who bullied sometimes or frequently.
Viljoen, O'Neill and Sidhu, 2005 ^a	Incarcerated adolescents (<i>M</i> = 18.7; 13–19 years) in Canada <i>N</i> = 244	Victimization scale measured verbal (3-item), physical (3-item) in custody Bullying scale measured the same items as the victimization scale	Multiple items from the YRBS: suicide ideation, suicide planning, suicide attempts, suicide attempts while in a youth custody center, self-harm while in a youth custody center, etc.	Girls were more likely to report being involved with bullying, particularly as victims, and being bullied by sexual touching and comments. Victims reported higher rates of suicidal behaviors than uninvolved.	37% were bully-victims, 32% were bullies, 8% were victims, and 23% were uninvolved.

NOTE: ^a These studies were not conducted in school setting.

Table 2. More studies on bullying and suicide by gender after Holt et al. (2015)

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Arango et al., 2016 a	Adolescents (M = 13.6; 12–15 years) in emergency department in US N = 321	The Peer Experiences Questionnaire measuring verbal, relational, and physical bullying victimization (9-item) and perpetration (9-item) during the past 4 months; Another measure asking cyberbullying (8-item); Dividing the participants into suicidal attempt group, suicide ideation only group, and non-suicidal group	Three binary items from the Columbia Suicide-Severity Rating Scale: Screen Version (CSSRS) measuring suicide ideation and attempts in the past 2 weeks	Girls reported more suicide ideation than boys. Boys and girls reported similar levels of bullying perpetration and victimization, except for higher relational victimization for girls. Boys were more likely to be in suicide attempt group relative to the suicide ideation group. Girls were more likely to be in either suicide attempt group or suicide ideation group relative to the non-suicidal group.	Higher levels of victimization and perpetration were associated with suicide ideation and attempts. The relationship between verbal victimization and being in the suicide ideation or suicide attempts groups was stronger for boys.
Barzilay et al., 2017	Students (M = 14.9 years) in 10 European countries N = 11,110	10 binary questions from the Global School-based Health Survey (GSHS) asking physical, verbal, and relational bullying victimization in the past 12 months	Two items from the Paykel Hierarchical Suicidal Ladder scale asking suicide ideation and suicide attempts in the past 2 weeks	Boys were more likely to report physical and verbal victimization, whereas girls were more likely to report relational victimization and suicide ideation and attempts.	Boys and girls did not differ in reporting multiple victimization.
Kelly et al., 2015	Secondary school students (12–15 years) in Australia N = 1,588	The revised Olweus Bully/Victim scale measuring bullying victimization and perpetration in the past 6 months	An item from the Brief Symptom Inventory (BSI) measuring suicide ideation in the past 6 months	No gender difference for victims, but more boys were in the bully and bully-victims groups. Bully-victims reported the highest suicide ideation than victims and bullies.	Suicide ideation increased the odds of being a bully-victim compared to being a bully or a victim.
Klomek et al., 2018	Students (M = 14.8 years) in 10 European countries N = 2,933	10 binary questions from the GSHS asking physical, verbal, and relational bullying victimization in the past 12 months at the baseline (T1) and one more measure after 3 months (T2)	Two items from the Paykel Hierarchical Suicidal Ladder scale asking suicide ideation and suicide attempts in the past 2 weeks at the 3-month follow-up (T2) and 12-month follow-up (T3)	No gender differences in suicide ideation and suicide attempt identified. Physical victimization at T1 and T2 led to suicide ideation and attempts at T2 and T3, respectively. Suicide attempt at T1 and T2 led to physical victimization at T3.	Chronic relational victimization led to suicide ideation and chronic physical victimization led to suicide attempt as compared with sporadic and no victimization.

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Lereya et al., 2015 – Study 1	Children in UK (cohort study) N = 4,026	Assessed at age 8, 10, and 13 years by the Bullying and Friendship Interview Schedule (9-item scale measuring overt and relational bullying victimization)	Assessed at age 18 years by the Clinical Interview Schedule-Revised (CIS-R; having two questions asking the presence and frequency of self-harm in the past 12 months)	Girls reported higher rates of self-harm than boys. Boys reported higher rates of being bullied than girls. An increased risk of young adult self-harm in children who were bullied by peers.	
Lereya et al., 2015 – Study 2	Children in North Carolina (cohort study) N = 1,420	Assessed annually between ages 9 and 16 years by children and their parents using the Child and Adolescent Psychiatric Assessment (CAPA)	Assessed at age 18 years by the Clinical Interview Schedule-Revised (CIS-R; having two questions asking the presence and frequency of self-harm in the past 12 months)	Boys reported higher rates of self-harm than girls. No gender differences in bullying victimization. An increased risk of young adult self-harm in children who were bullied by peers.	
Massing-Schaffer et al., 2018 a	Girls having mental health concerns in US (M = 14.6; 12–18 years) N = 160	Assessed at the end of the first 9 months (Period 1) using the Youth Life Stress Interview measuring relational victimization in the past 9 months	Assessed every 3 months in the second 9 months (Period 2) using the Self-Injurious Thoughts and Behaviors Interview measuring suicide ideation and attempts	No result on gender differences (girls-only study) Higher relational victimization experience was related to increased risk for suicide attempts, even controlling for prior suicide ideation and attempts.	Prior suicide ideation was associated with higher odds of subsequent suicide ideation.
Nikolaou, 2017	Students in (14–17 years) 1991–2015 biennial YRBS data of 34 states in US. N = 1,491	A binary question in YRBS asking cyberbullying victimization during the past 12 months	4 measures of nonfatal suicidal behaviors asking suicide ideation, suicide planning, suicide attempt, and nonfatal injury after suicide attempt in the past 12 months	Cyberbullying increased suicide ideation by 14.5 percentage points and suicide attempts by 8.7 percentage points.	These effects were stronger for boys than for girls.
Reed, Nugent and Cooper, 2015	Students in (14–17 years) 2011 Youth Risk Behavior Surveillance System data (YRBSS) in US. N = 15,425	Two binary questions in YRBSS asking traditional and cyberbullying victimization in the past 12 months	Three binary questions in YRBSS asking suicide ideation, suicide planning, and suicide attempts	Girls who reported cyberbullying victimization showed higher rates of suicidal behaviors compared to their male counterparts.	Suggesting a possibility of spontaneous suicide attempts by students who reported victimization but did not report suicide ideation and suicide planning.
Sibold et al., 2015	Students (14–17 years) in 2013 YRBS N = 13,583	Two items in YRBS measuring traditional and cyberbullying (merged into a single measure)	Two items measuring suicide ideation and two items measuring suicide attempts in the past 12 months.	Girls reported higher suicide ideation and attempts. Bullied students were 3 times as likely to report suicide ideation and attempts.	22% reported suicide ideation and 8% reported suicide attempts.

Table 2. (Continued)

Authors, year	Sample	Bullying measures	Suicide measures	Results on gender differences	Other results
Sigurdson et al., 2018	Students (M = 13.7; 12–15 years at baseline) in Norway (cohort study) N = 2,464	Assessed in 1998 asking three questions of bullying victimization in the past 6 months	Assessed in 2012 asking suicide ideation (5-item), self-harm (1-item), and suicide attempts (1-item)	Bullied girls reported a decrease in suicide ideation from adolescence to adulthood, while bullied boys reported an increase in suicide attempts in the same period.	Bullied participants reported higher suicide ideation, self-harm, and suicide attempts regardless of gender.
Vergara et al., 2019 a	Adolescents (M = 15.3; 13–18 years) having non-suicidal self-injury past year N = 223	Revised Peer Experiences Questionnaire (RPEQ) asking bullying victimization and perpetration in the past 12 months	Beck's Scale for Suicide Ideation asking suicide ideation in the past week; Self-Injurious Thoughts and Behaviors Interview (SITBI) asking suicide ideation (past month and lifetime) and suicide attempt (past month and lifetime)	No gender difference in suicidal behaviors identified. Compared with participants not having lifetime suicide attempts, participants with lifetime suicide attempt reported higher bullying victimization and perpetration. Bullying perpetration was related to larger number of past month suicide attempts.	Bullying victimization was related to greater non-suicidal self-injury behaviors in the past month.

NOTE: ^a These studies were not conducted in school setting.

- Toxicology ($N = 1,217$ for those cases having toxicology available)
 - 28.3% ($n = 345$) were opiate tested and 7.8% ($n = 95$) were opiate present
 - 38.6% ($n = 470$) were alcohol tested and 19.8% ($n = 241$) were alcohol presented
 - 38.8% ($n = 472$) were marijuana tested and 21.5% ($n = 262$) were marijuana presented
 - 25.9% ($n = 315$) were cocaine tested and 3.1% ($n = 38$) were cocaine presented
 - Note that there are many missing values on the toxicology test results especially in recent years. For example, the proportion of missing opiate test results were 38.5% in 2010 and 20.9% in 2011, but 91.4% in 2015 and 94.1% in 2016. This is largely because of the way the data were collected. In 2010-2011, only data on the drug classes was entered and no data on specific substances was entered. Recently, data on all the substances that were positive was entered, which led to a larger number of drug classes.
- 6.6% ($n = 93$) had problems at school (bullying, poor grades, performance pressures, etc.), and 1.9% ($n = 27$) of cases coded this school problem as a “crisis.”
- 4.3% ($n = 61$) were veterans.

3.2.4. Bullying-Related Cases in OH-VDRS

When analyzing coroner/medical examiner/law enforcement narratives in the OVDRS data, a total of 28 bullying-related cases (10-24 years old) were identified between 2010 and 2016. Most ($n = 24$) were deaths by suicide, one case was homicide, and three cases were of undetermined intent. 23 cases indicated youth were bullied, two cases indicated youth were bullying other youth, and three cases provided unclear data on the perpetration versus receipt of bullying. Of these, most ($n = 19$) were male.

Other noticeable findings include: (a) most cases (60.7%, $n = 17$) were between 13 and 15 years old. (b) About half (46.4%, $n = 13$) left suicide notes (or texts, social media posts). (c) About 45% ($n = 12$) had diverse family issues (parents' divorce, fight with other family members, etc.). (d) More than half (53.6%) died by self-inflicted hanging and 39.3% died by gunshot wounds. (e) About 45% ($n = 12$) were either depressed or had clinical depression. (f) About 20% ($n = 6$) had difficulty with their boyfriend or girlfriend proceeding their death.

CONCLUSION

While there is not a 1:1 correspondence between bullying and suicide, there does appear to be a relationship. Understanding how bullying impacts female and male youth differently, and how this relates to suicidal intent as well as to death by suicide is an area for further inquiry. Generally, girls are more likely to be victims of bullying and boys are more likely to be perpetrators of bullying. Perpetrators (whether boys or girls) are more likely to have suicidal thoughts and to act on those thoughts. The exception is boys of sexual minority orientation, who are more likely than other boys to be victims of bullying and more likely to have suicidal thoughts and actions. Among youth who die by suicide, more boys than girls are represented; this is true among those whose death is related to bullying as well.

BIOGRAPHICAL SKETCH

Jane Timmons-Mitchell, Ph.D.

Affiliation: Case Western Reserve University, Senior Research Associate, Begun Center for Violence Prevention, Associate Clinical Professor of Psychology, School of Medicine

Education: Wellesley College, Wellesley, MA.

May, 1977. BA with majors in psychology and English.

Magna Cum Laude with honors in psychology.

Case Western Reserve University, Cleveland, OH.

January, 1980. MA in psychology/

August, 1982. PhD in clinical psychology from APA approved program.

Concentration in clinical child psychology.

Internship: University Hospitals of Cleveland, Cleveland, OH. September, 1981-August, 1982. APA approved internship with concentration in child psychology.

Post-Doctoral Fellowship: Department of Family Medicine, CWRU School of Medicine, Cleveland, OH.

2000-2001. Substance Abuse Prevention, Faculty Development Program, funded by SAMHSA (Substance Abuse and Mental Health Services Administration).

Business Address: 11402 Bellflower Rd. Cleveland, OH 44106.

Research and Professional Experience:

1) Research:

2018-2021. Mental Health Awareness Training for National Guard Veterans, the Ohio Suicide Prevention Foundation, Substance Abuse and Mental Health Services Administration (SAMHSA). Principal Investigator, 10% effort.

2015-2018. Health Resources and Services Administration Project IMPACTT awarded to Tatiana Falcone, MD, PI, Cleveland Clinic Foundation. Sub-award PI, 25% effort.

2015-2020. Ohio's Campaign for Hope, the Ohio Suicide Prevention Foundation, Substance Abuse and Mental Health Services Administration. Principal Investigator, 35% effort.

2013-2016. Health Resources and Services Administration Project CARE awarded to Tatiana Falcone, MD, PI, Cleveland Clinic Foundation. Sub-award PI, 25% effort.
2011-2014. Ohio's Campaign for Hope, the Ohio Suicide Prevention Foundation, Substance Abuse and Mental Health Services Administration. Principal Investigator, 30% effort.
Health Resources and Services Administration Project COPE, awarded to Tatiana Falcone, M.D, PI, Cleveland Clinic Foundation. Sub-award PI, 20% effort.
Cleveland Heights-University Heights City School District, U.S. Department of Education Safe Schools Healthy Students initiative. provided MST by contract.
Participated in evaluation of effectiveness of grant program.

2) Teaching:

2014, 2013, 2012, 2011, 2010, 2009, 2008, 2007, 2006, 2005, 2004, and 2003 Fall, winter, spring and summer semesters. SRCH/SASS 530: Practice Evaluation, (Jack, Joseph and Morton) Mandel School of Applied Social Sciences, Case Western Reserve University, Full-time Program and Intensive Weekend Program. Graduate course on single system evaluation methods; focus on evidence-based practices for social workers.
2011, Spring semester. SBS 80100. Emerging Issues in Prevention Science, College of Public Health, Kent State University. Doctoral course providing an in-depth analysis of current issues in prevention science, with an emphasis on emerging areas of research. Created and taught initial course offering.

3) Entrepreneurship:

March, 2001 to present. Founded Junction Psychological Services Corporation; President and CEO offering a range of psychological services

4) Professional Service:

2017 to present. Reviewer, Journal of Attention Disorders.
1995 to present. Reviewer, Child Maltreatment, The Journal of the American Professional Society on the Abuse of Children.
2011 to present. Reviewer, Archives of General Psychiatry.
2013 to present. Reviewer, Frontiers in Psychology.
2015 to present: Reviewer, JAMA Psychiatry.
2013, 2014. Peer Reviewer, U.S. Department of Justice, Office of Juvenile Justice and Delinquency Prevention, Field Initiated Research Grants.
2012. Peer Reviewer, U.S. Department of Justice, Bureau of Justice Assistance, FY 2012 Byrne Criminal Justice Innovation Program.
2008. Peer Reviewer, U.S. Department of Justice, Bureau of Justice Assistance, FY 2008 Justice and Mental Health Collaboration Program.
2003. Peer Reviewer, GAINS Center for Mental Health and Juvenile Justice.
2002. Peer Reviewer, U.S. Department of Health and Human Services, Graduate Psychology Education Program.

Professional Appointments:

January, 2003 to present. Case Western Reserve University, Mandel School of Applied Social Sciences, Adjunct Professor.

July, 2001 to present - Case Western Reserve University School of Medicine, Cleveland, OH. Associate Clinical Professor of Psychology, Department of Psychiatry.

July, 2010 to June, 2011 - Kent State University, College of Public Health, Adjunct Professor, Social and Behavioral Sciences.

May, 2000 to April, 2001 - Case Western Reserve University School of Medicine, Cleveland, OH, Associate Professor of Psychology, Department of Psychiatry,

September, 1988 to May, 2000 - Case Western Reserve University School of Medicine, Cleveland, OH, Assistant Professor, Department of Psychiatry. University Hospitals of Cleveland, Cleveland, OH.

1988-1990. Associate Medical Staff.

1990 – 2001. Member, Medical Staff. Case Western Reserve University School of Medicine, Cleveland, OH.

1987-1988. Senior Clinical Instructor, Department of Psychiatry.

Honors:

Graduate Alumni Award, Case Western Reserve University, 1981 and 1982.

Sigma Xi Scientific Honorary Society, 1977.

Advisor, First Place Student Poster, All-Ohio Community Psychiatry Institute, 1997.

SAMHSA Administrator's Award, Honorable Mention, for Cleveland Heights University Heights School District Safe Schools Healthy Students grant: expanding mental health services to students, 2005.

Researcher of the Year Award, Family Services Research Center, Medical University of South Carolina, and MST Services, 2006.

National Association of Professional Women, 2011-2012, 2012-2013 Woman of the Year, Psychology, Ohio.

Marquis Who's Who Lifetime Achievement Award, 2017.

Chapter 38

THE INFLUENCE OF PARENTING ON SCHOOL BULLYING: DOES CHILD GENDER MATTER?

Karyn L. Healy*, PhD

Parenting and Family Support Centre, School of Psychology,
The University of Queensland, Brisbane, Queensland, Australia

ABSTRACT

School bullying has serious consequences for children and teenagers. Previous efforts to reduce bullying have focussed almost exclusively on whole school anti-bullying interventions. Recent meta-analyses show that, in general, these interventions produce only modest improvements. A substantial body of research examines the relationship between parenting and children's peer relationships and involvement in bullying. This chapter reviews the theory and evidence of how parenting influences children's involvement in bullying at school, and considers whether child gender influences this relationship. Some distinctions can be made on the basis of gender. However, the most pressing issue with respect to gender is the serious mental health problems of gender minority students, who are affected by peer victimization. Research suggests that parental support is an important source of support for these vulnerable youth. Recommendations are made for better engaging parents to prevent children's involvement in bullying.

Keywords: parenting, bullying, victimization, child gender, peer relationships

INTRODUCTION

Bullying is hurtful behavior that can be direct (physical or verbal) or indirect relational (e.g., deliberate exclusion or gossiping). It can be conveyed in person or through technology (cyber bullying). On the basis of previous recommendations, Vivolo-Kantor, Martell, Holland and Westby (2014) identified five criteria for behavior to qualify as bullying: a power

* Corresponding Author's Email: k.healy@psy.uq.edu.au.

imbalance, intent to harm, experience of harm by the victim, repetition, and aggression. However, Vivolo-Kantor et al., found that most studies of bullying do not operationalize all of these criteria. Despite some variations in definitions across the field of study, it is clear that school bullying is a serious problem, especially for victims. This chapter examines how parenting influences children's involvement in bullying, and whether child gender makes a difference to this relationship.

There is little doubt that bullying causes great harm. Being bullied greatly increases a child's risk of ongoing mental health problems including depression, anxiety and psychosis (Arseneault et al., 2008; Fisher et al., 2012; Schreier et al., 2009), and also leads to reduced academic achievement (Bowes et al., 2013), increased externalizing problems (Reijntjes et al., 2011; Perren, Ettekal & Ladd, 2012), and loss of friendships (Ladd, Kochenderfer & Coleman, 1997). Negative mental health consequences of childhood bullying in the form of depression have been tracked decades later, well into adulthood (Sourander et al. 2007; Farrington, Loeber, Stallings, & Ttofi, 2011). Children and teenagers who perpetrate bullying are also at heightened risk of later involvement in crime, drug abuse and adult arrest (Schwartz, Lansford, Dodge, Pettit & Bates, 2018; Sourander et al., 2007; Ttofi, Farrington, Lösel & Loeber, 2011; Wolke, Copeland, Angold & Costello, 2013). Even students who witness bullying experience stress (Rivers, Poteat, Noret & Ashurst, 2009).

Children who are bullied have been described as either passive or aggressive victims. Most are passive victims who tend to be submissive and do little to encourage bullying (Olweus, 1978). On the other hand, aggressive victims of bullying, also known as provocative victims or "bully-victims" (Boulton & Smith, 1994) tend to lash out angrily and start fights as well as get picked on (Schwartz, Dodge, Pettit & Bates, 1997). According to meta-analyses conducted by Reijntjes and colleagues (Reijntjes, Kamphuis, Prinzie & Telch, 2010; Reijntjes et al., 2011), both internalizing (e.g., depression or anxiety) and externalizing responses (e.g., angry lashing out) lead to increased risk of further victimization, which can become an entrenched pattern for some children.

In response to the serious risk bullying poses, a plethora of school anti-bullying interventions have been developed. Meta-analyses show that, in general, these programs produce small reductions in bullying and victimization (Merrell, Guelnder, Ross, & Isava, 2008; Ttofi & Farrington, 2011). One recent meta-analysis that included children's year level as a moderator found that, although school programs had a small positive effect in elementary school, there was overall no benefit for secondary school students (Yeager, Fong, Lee & Espelage, 2015). Clearly more needs to be done to address the serious risk bullying poses to students.

Recent research has turned to what parents can do to supplement efforts of schools in addressing the risk of bullying. This chapter reviews evidence and theory of how parenting influences children's and teenagers' involvement in school bullying, and examines what is known about how child gender affects this relationship. We will first briefly review the relationship between gender and children's involvement in school bullying. We will then consider theory and then review the evidence for the relationship between parenting and children's involvement in bullying. Finally, we will look at how the relationship, between parenting and children's involvement in bullying, might differ depending on gender. Within these early sections we will consider only the male/female gender dichotomy, as this is the focus of almost all research until very recently. We will then examine recent research on teenagers who are gender diverse, before drawing conclusions and making recommendations.

CHILD GENDER AND BULLYING

Decades of research have examined the question of whether and how child gender affects children's involvement in bullying. The weight of evidence suggests that, in general, boys have a higher involvement in bullying than girls, both as perpetrators and victims. However, this generalization varies, depending on the type of bullying and the nature of the child's involvement.

Several meta-analyses and structured reviews provide information about how gender affects children's involvement in bullying. A meta-analysis by Cook, Williams, Guerra, Kim and Sadek (2010), found that, overall, boys had a higher level of involvement in bullying than girls, as either a victim or perpetrator. For being a passive victim, the gender difference was weak. The gender difference was larger (consistent with a small effect size) for both aggressive victims of bullying and for student who bully only.

In a review of individual risk factors for perpetration of school bullying, Farrington and Baldry (2010) also found that, in general, boys bully more than girls, and that the gender difference was greatest for direct bullying (e.g., physical aggression or threats). Farrington and Baldry concluded there was much less, or no difference, for perpetration of indirect relational bullying.

There have been similar findings in perpetration of aggression, a construct that overlaps with bullying. A meta-analysis by Card, Stucky, Sawalani and Little (2008) found that boys perpetrated direct aggression (including verbal) more than girls, equivalent to a medium effect size. They found that girls perpetuated indirect (relational) aggression slightly more than boys, but that the differences, although significant, were trivial. Card et al. also examined whether age interacts with gender to predict involvement in bullying, but found it did not affect the magnitude of relationship for either direct or indirect aggression.

Similarly, a meta-analysis of gender differences in victimization found that boys reported experiencing more physical bullying than girls whereas, for relational victimization, there were negligible gender differences (Card, Isaacs & Hodges, 2007). However, this may depend on severity of victimization; Kochenderfer and Ladd (1997) found that, for highly victimized children, physical bullying was equally common for boys and girls.

As cyber bullying is a relatively recent phenomenon, it tends to have been examined in separate studies. However, evidence suggests it is highly correlated with face-to-face bullying. In a meta-analysis of studies of cyber bullying, Guo (2016) found that the strongest predictors of online bullying were measures of offline bullying, and that the strongest predictor of online victimization was offline victimization. Similarly, Fanti, Demetriou and Hawa (2012) found that school bullying and cyber bullying were highly correlated cross-sectionally and longitudinally, as were school victimization and cyber victimization. However, a large cross-sectional study suggested that a higher proportion of children may be involved in cyber bullying as bully-victims than is the case with offline bullying (Mishna, Khoury-Kassabri, Gadalla & Daciuk, 2012).

Recent meta-analyses on cyber bullying provide information about the relevance of child gender. Guo (2016) reported a small to medium effect of gender on perpetration of bullying, meaning that more boys perpetrate cyber bullying than girls. There was also a relatively small, yet significant, effect on cyber victimization, with more females identified as victims. Similarly, Barlett and Coyne (2014) conducted a meta-analysis on perpetration of cyber

bullying and found that males were slightly more likely to cyber-bully than females; however, this was moderated by age, with females reporting higher levels during early to mid-adolescence and males reporting higher levels in late adolescence. This pattern is similar to offline bullying, with more males than females in general perpetrating bullying. Smaller gender differences in cyber bullying may reflect the similarities between cyber bullying and indirect relational bullying (Barlett & Coyne, 2014).

Other studies have provided information on other aspects of involvement in bullying with regards to gender. A meta-analysis by Nickerson, Aloe and Werth (2015) examined research on the association between empathy and defending behavior of bystanders in bullying. Of the 20 studies included, only six separated findings according to gender, and, based on this small number, moderator analyses were not significant. Future research may provide further clarification on this.

Although not explicitly examined in any meta-analysis to my knowledge, some research suggests that bullying occurs more often within same gender groups, at least at younger age levels. Bullying has been reported as more common within same gender groups for preschool children (Crick, Casas, & Ku, 1999; Crick et al., 2006). Also, a study of elementary school children aged between 6.5 and 10.8 years, found that indirect social bullying occurred mainly in same gender groups (Von Marées & Petermann, 2010). However, in adolescence, a form of bullying referred to as sexual bullying, consisting predominantly of verbal harassment, has been reported to be most commonly perpetrated by adolescent boys towards girls (Pellegrini, 2002; Shute, Owens, & Slee, 2008).

THEORY OF HOW PARENTING INFLUENCES CHILDREN'S INVOLVEMENT IN BULLYING

Most school bullying happens at school, and most parent-child interactions occur outside school. So, the link between parenting and school bullying requires explanation. We will now examine theory relevant to how and why parenting would be expected to influence children's involvement in bullying.

The major theories of child development acknowledge the central role of parents in shaping the child's skills and behavior that are transferred into relationships with others, including peers. According to attachment theory, children develop an internal representation (or template) of relationships from their earliest relationships with attachment figures (usually their parents), which they then apply to others (Bowlby, 1969). Similarly, social learning theory proposes that children learn how to behave towards others through behaviors modelled by parents and siblings, and generalize these to other environments and relationships with peers and friends (Bandura, 1977). Consistent with both attachment and social learning theory, Parke, Ladd and colleagues theorized that children learn the social skills needed for successful peer relationships through daily interactions within their families (Parke & Ladd, 1992). Hence, children can learn behaviors within their family that can be either positive or negative when applied to peer relationships.

If the family does not provide an opportunity for the child to develop the skills to build relationships and to resolve problems, the child will not be well equipped to develop quality relationships with others, including peers at school. This could influence the quality of

friendships the child is able to develop. Given that friendships help protect children from bullying (Fox & Boulton, 2006), lack of quality friendships could leave a child vulnerable to victimization.

The theory of operant conditioning suggests further mechanisms for how behaviors can be shaped in both family and peer settings. Relevant to bullying perpetration, Patterson (1982) described how children learn coercive behaviors within their family. Patterson explained that, if a parent escalates, and threatens or enacts aggression towards the child, most children will submit, but some children will aggress back. If the parent submits, in response to child aggression, the child is encouraged to aggress next time there is conflict. However, if the parent continues to aggress, this can lead to an escalation in violence. Either way, the child is learning to use aggression in response to conflict.

Coercive parenting could also reinforce the submissive behaviors relevant to passive victims of bullying. Children may be encouraged to show submissive behavior in response to a parental threat of aggression, if this leads to the parent ceasing their threats. The child may then generalize this submissive behavior into peer relationships. On the other hand, supportive family relationships characterized by warmth, respectful communication and appropriate assertion could also be learnt in the family context and transferred into peer relationships, assisting the child in developing warm respectful relationships with peers.

THE RELATIONSHIP BETWEEN PARENTING AND CHILD INVOLVEMENT IN BULLYING

A substantial body of literature examines the relationship between parenting and children's involvement in bullying. We will first examine research relevant to the relationship between parenting and children's peer victimization, and then turn to evidence of the relationship between parenting and children's perpetration of bullying towards peers.

Parenting and Children's Victimization by Peers

Lereya, Samara and Wolke (2013) conducted a systematic review of longitudinal and cross-sectional studies of the association between parenting and peer victimization. They found that children who have been victimized (including those who also bully) were more likely to have been exposed to negative parenting including abuse, neglect and maladaptive parenting. The effect sizes were strongest for bully-victims. Similarly, the meta-analysis by Guo (2016) on studies on cyber bullying found that negative family environment had small but significant effects on cyber victimization. Provocative victims have been described as having more severely problematic family functioning compared to families of passive victims, bullies and uninvolved children (Bowers, Smith & Binney, 1994; Rigby, 1994). A longitudinal study by Schwartz et al. (1997) found that children who emerged as provocative victims had experienced more punitive, hostile and abusive early family experiences than children who were passive victims, bullies or uninvolved in bullying.

On the other hand, Lereya et al. (2013) also found that positive parenting, including a warm, supportive relationship, good communication and supervision, protected children

against victimization by peers. Consistent with this, in a large-scale longitudinal study, Bowes et al. (2013) found that family environmental factors, including low maternal warmth, increased children's vulnerability to chronic victimization. Similarly, Fanti et al. (2012) conducted a longitudinal study with a large sample of adolescents in Cyprus, and found that family support protected adolescents living in single-parent households from cyber victimization when their friendships were not supportive. The importance of a warm supportive parent-child relationship is also reinforced by studies from an attachment perspective. For instance, Murphy, Laible and Augustine (2017) found that teenagers who reported greater attachment security to parents reported less victimization.

Although most studies in parenting are conducted primarily with mothers, there are several cross-sectional studies specifically focusing on fathers; these studies reinforce the importance of positive parental involvement and support. Attachment and positive involvement with fathers as well as mothers are associated with lower levels of victimization (Flouri & Buchanan, 2003; Liu, Yang, Zhou, Wang & Su, 2012). Papadaki and Giovazolias (2015) found that paternal acceptance moderates the impact of maternal rejection on risk of involvement in bullying (as either a victim or perpetrator).

Other studies provide further nuances in understanding the types of negative and positive parenting behaviors associated with risk of child victimization. Studies generally show that parenting that is less child responsive and more over-directive or over-protective is associated with higher risk of child peer victimization. Cross-sectional studies have found that parents of bullied children tend to be overly protective (Bowers et al., 1994) and to solve the child's problems rather than encourage independence (Oliver, Oaks, & Hoover, 1994). Parents of children who are victimized have been found to be high on "intrusive demandingness" and low on "child responsiveness" (Ladd & Ladd, 1998). More recently, Boel-Studt and Renner (2013) found that, for teenagers, parental criticism was associated with physical victimization, and higher parental monitoring was associated with psychological victimization. In a large-scale survey of students from Years 6 to 10 in the USA, Nansel et al., (2001) found that high levels of parental over-involvement were positively associated with victimization (for both passive victims and bully-victims).

These parental behaviors of criticism, over-protection and intrusiveness could all interfere with children and teenagers learning skills to look after themselves, which could in turn, interfere with development of peer relationships. However, caution needs to be taken in interpreting these studies as they are cross-sectional, and research shows that, just as parents influence children's behavior, children also influence parents' behavior (Sanson, Letcher & Havighurst, 2018). It would be natural for a parent who was concerned about their child being bullied to respond by staying close, providing more supervision and restricting the child's freedom. This, in turn could prevent the child from learning to look after themselves, and could prevent them from forming friendship with peers, which protect against victimization (Fox & Boulton, 2006).

There is other research that identifies additional parenting behaviors that reduce risk of victimization. McDowell and Parke (2009) identified three distinct paths through which supportive parenting can positively impact children's social skills and acceptance by peers. The first path, as discussed already, is through the quality of the relationship itself. Having a warm, supportive relationship with a parent helps provides children with a template of what supportive relationships are like, and provides them with examples of how to achieve this. The second path is through directly teaching social skills within the family. This is consistent with previous

research that has identified poor social competence as one of the strongest predictors for being bullied, and also a predictor of bullying behavior (Cook et al., 2010). The final path is through the gatekeeper role that parents exert (consciously or unconsciously) on children's opportunities to form friendships, including choices of neighborhoods and schools, as well as the practical support they provide for children to spend time with peers (e.g., through play-dates). McDowell and Parke (2009) found that all three of these paths contributed to children's later social skills and acceptance by peers.

Building on the work of McDowell and Parke (2009), and other research, Healy, Sanders and Iyer (2015) defined a type of parenting, facilitative parenting, proposed to protect children against victimization by peers. Facilitative parenting combines high levels of warm support with encouragement of independence rather than being overly controlling; it also includes the coaching of social skills and deliberate creation of opportunities for friendships with peers to develop. Healy et al., (2015) found that facilitative parenting discriminated between children teachers reported were bullied, from those who were not. In a longitudinal study of children with a history of victimization, Healy and Sanders (2018) found that facilitative parenting protected children from ongoing victimization mediated through improved peer acceptance.

Parenting and Children's Perpetration of Bullying

There is less research on the relationship between parenting and children's perpetration of bullying. Children's perpetration of bullying has been associated with lower levels of warmth, higher levels of harsh, coercive discipline including physical punishment, and lower levels of supervision (Atik & Güneri, 2013; Baldry & Farrington, 2000; Demaray & Malecki, 2003; Loeber & Dishion, 1984). These same parenting styles have also been implicated in children's callous-unemotional traits (Waller, Gardner et al., 2015) which are characterized by low empathy (Golmaryami et al., 2016).

It is easy to see how this combination of parenting styles could support the development of bullying behavior in children. Children would learn coercive behavior through their parent modelling coercion. Lack of parental supervision would allow children to act coercively towards siblings and peers without correction (Olweus, 1980). Also, a lack of parental warmth leads to poorer development of empathy in children (Waller, Shaw, Forbes, & Hyde, 2015), which allows children to overlook the hurt they cause peers.

Similar parenting styles have been associated with perpetration of cyber bullying. The meta-analysis by Guo (2016) on cyber bullying reported that negative family environment had a small but significant effect on cyberbullying perpetration. Parental warmth and positive family relationships has also been found to be negatively associated with perpetration of cyber bullying. In a large longitudinal study of adolescents in Cyprus, Fanti et al. (2012) reported that positive family support protected against both perpetration of cyber bullying as well as cyber victimization.

Two other studies have found that cyber bullying is associated with high levels of parental control. Buljan Flander, Dugić and Handabaka (2015) reported that for adolescents, high levels of parental control reported by students were associated with involvement in cyber victimization, as well as perpetration of bullying. Le et al. (2017) reported that for teenagers in Vietnam, there was an association between perpetration of bullying and higher levels of parental control. The relevance of parental control would seem to be inconsistent with other

research that shows that bullying perpetration is associated with lack of supervision. This difference may be explained by the relatively high overlap in cyber bullying in students who both bully and are victimized (Mishna et al., 2012).

The relevance of warm responsive parenting to children's perpetration of bullying as well as victimization, is consistent with both attachment theory and social learning theory; if a child forms a poor-quality relationship with their parent, they may have limited capacity to understand, empathize with, and form supportive relationships with peers. Murphy et al., (2017) found that teenagers who reported greater attachment security to parents, not only reported less victimization; they also reported less perpetration of bullying and greater defending of victims.

PARENTING AS A PROTECTIVE FACTOR FOR ADVERSE CONSEQUENCES OF INVOLVEMENT IN BULLYING

As well as reducing the risk of children's involvement in bullying, there is substantial evidence that positive parenting also protects children from some negative consequences of being bullied. In a large-scale longitudinal study, Sapouna and Wolke (2013) investigated factors that distinguished adolescents who demonstrated lower-than-expected increases in depression and delinquency after being bullied. Lower levels of conflict with parents, and lack of victimization by siblings, were amongst the factors that predicted lower-than-expected levels of both depression and delinquency following victimization. There are also many cross-sectional studies that are consistent with this finding. A large study by Klomek et al., (2016) found that the association between victimization and self-injurious behavior in European adolescents was moderated by parent and peer support. Other cross-sectional studies have found that supportive parental relationships protect adolescents against internalizing problems (Ledwell & King, 2015) and mental health problems (Stadler, Feifel, Rohrmann, Vermeiren & Poustka, 2010) associated with victimization by peers.

Recent longitudinal research has investigated the mechanisms through which positive parenting protects children against the internalizing consequences of bullying. Bowes, Maughan, Caspi, Moffitt and Arseneault (2010) found that warm, responsive parenting moderates the internalizing consequences of victimization over time. However, another large three-wave longitudinal study, found that, rather than attenuating the negative impact of victimization, supportive parenting had a direct positive impact on depression over time (Bilsky et al., 2013). Consistent with this, Healy and Sanders (2018) found that facilitative parenting (parenting that is warm, and supportive of children's peer relationships) had a direct effect on later depression. Whether positive parenting affects internalizing problems directly or through mitigating the impact of victimization, evidence suggests it helps reduce the risk of internalizing problems following victimization.

In a cross-sectional study involving a very large representative sample of European adolescents, Barzilay et al., (2017) examined moderators of the associations between three types of bullying victimization (physical, verbal, and relational) with suicide ideation and attempts. Verbal victimization was associated with suicide ideation amongst adolescents with depression who perceived low parental support. Verbal victimization was associated with suicide attempts among adolescents with anxiety who perceived low parental support. In

summary, there is a great deal of evidence that supportive parenting protects children from some of the most serious adverse impacts of bullying.

DOES GENDER MODERATE THE RELATIONSHIP BETWEEN PARENTING AND CHILDREN'S INVOLVEMENT IN BULLYING?

So, supportive parenting reduces the risk of children being involved in bullying, and mitigates some of the most serious consequences of bullying. Various forms of negative parenting are associated with increased risks of involvement of children and teenagers in bullying as victims and perpetrators. We will now examine whether and how child gender affects the relationship between parenting and children's involvement in bullying, as victims and perpetrators.

Gender as a Moderator of the Relationship between Parenting and Victimization

There are many cross-sectional studies that investigate whether gender moderates the relationship between parenting and victimization. Early cross-sectional studies suggested some gender differences in the relationship between parenting and children's victimization. Maternal overprotection was found to be associated more with victimization of boys (Finnegan, Hodges, & Perry, 1998; Ladd & Ladd, 1998), whereas coercive parenting, parent-child conflict and intrusive demandingness were reported as associated with victimization of girls (Finnegan et al., 1998; Rigby, 1994). Finnegan et al. (1998) proposed that maternal behavior might impact differentially on boys and girls; for boys, a threat to autonomy could increase the risk of victimization, whereas for girls, reduced connectedness could increase the risk of victimization.

On the other hand, Shields and Cicchetti (2001), found that child maltreatment placed both boys and girls at greater risk for peer victimization. More recently, Lucas, Jernbro, Tindberg and Janson (2016) confirmed, with a nationally representative sample of Swedish adolescents, that violence at home (including witnessing intimate partner violence) was associated with higher levels of both bullying victimization and bullying perpetration, with no differences across child gender.

Some recent cross-sectional studies have suggested that interactions involving child gender that are quite complex. Boel-Studt and Renner (2013) explored whether adolescent age and gender moderated the association between parenting behavior and risk of physical or psychological peer victimization. They reported that gender moderated the relationship between parental monitoring and risk of both physical and psychological peer victimization, with a stronger risk for girls. Murphy et al., 2017 found that, for adolescent males, but not females, greater peer attachment security predicted less bullying involvement for those with lower parent attachment security. You et al., (2015) investigated how mother, peer, and school attachment were directly and indirectly related to bullying behavior through empathy, and whether these relationships were moderated by gender, for young adolescents in Seoul. You et al. found that, for male students, greater school attachment was directly related to less bullying behavior and maternal and peer attachment had indirect effects on bullying behavior, mediated

by student cognitive empathy. For female students, greater maternal attachment was directly related to less bullying behavior, and peer attachment had an indirect effect on bullying behavior, mediated by student affective empathy.

The interactions described above are complex, and not clearly predictable or interpretable in terms of theory. We need to exercise caution in drawing conclusions about how variables affect each other over time from cross-sectional studies. For instance, Murphy found that higher levels of parental monitoring predicted higher levels of victimization based on cross-sectional data; perhaps it was the other way around: the child's victimization may have prompted higher levels of parenting monitoring over time rather than vice versa.

A recent longitudinal study sheds some light on this question. Wright (2017) studied how different parental strategies to regulate young adolescents' use of technology (i.e., instructive, restrictive, co-viewing) affected their perpetration of cyber bullying and cyber victimization, and how gender might impact these associations. Wright found that both the positive association between restrictive regulation and cyber victimization and the negative relationship between instructive regulation and cyber victimization, were stronger for girls than for boys. These interactions are theoretically plausible. If social media is a more important vehicle for relationship development for girls, restricting usage may prevent the development of supportive peer relationships which protect against victimization. However, instructions without restriction may enable girls to stay in touch with friends.

Gender as a Moderator of the Relationship between Parenting and Perpetration of Bullying

Several longitudinal studies have examined the impact of gender on relationships between parenting and child bullying behavior. Low and Espelage (2013) examined predictors of cyber bullying and other non-physical bullying perpetration in early adolescents over three time points, 6 months apart. They found that lower levels of parental monitoring were associated with higher levels of cyber bullying at Wave 3, via alcohol and drug use for White females only. Non-physical bullying perpetration was associated with both higher family conflict and lower parental monitoring, which were explained by hostility (for White males) and depressive symptoms (for African American males). Low and Espelage concluded that familial socialization is very important but mechanisms of influence can differ according to gender and cultural context.

In a large longitudinal study, Turns and Sibley (2018) investigated the relationship between parental spanking in early childhood and later child perpetration of bullying in Years 1, 3, 5 and 9 at school. They found that spanking at age 1 positively predicted childhood bullying at age 3 for boys and negatively predicted bullying for girls. This is consistent with cross-sectional research mentioned previously that found that coercive parenting was associated with victimization of girls more than boys (Finnegan et al., 1998; Rigby, 1994).

Atherton, Schofield, Sitka, Conger and Robins (2016) examined the relationship between unsupervised self-care and conduct problems of children of Mexican origin residing in the U.S. They found that unsupervised self-care was related to increases over time in conduct problems such as lying, stealing, and bullying, but only for boys. This seems to indicate that lack of parental monitoring is more of a risk factor for development of bullying behavior in boys than in girls.

GENDER MINORITIES AND INVOLVEMENT IN BULLYING

Historically, gender research has taken a purely binary view of gender (male or female). More recently, research has focused on adolescents who are transgender (i.e., who identify differently than their birth sex), intersex (i.e., born with a combination of male and female biological characteristics) and other individuals who do not identify with heterosexuality. The proportion of adolescents who do not identify with binary male/female gender is small. Clark et al., (2014) reported that, for a nationally representative high school sample of New Zealand students, 94.7% reported being non-transgender, 1.2% reported being transgender, 2.5% were unsure about their gender, and 1.7% did not understand the question.

Although small in number, transgender adolescents, and other adolescents in gender and/or sexual minority groups have much greater risk of serious mental health problems than other adolescents. Clark et al., (2014) found that adolescents who were transgender, unsure about their gender, or did not understand the question, reported higher levels of depression, suicide attempts and school bullying than other students. As many as 40% of transgender students reported significant depressive symptoms and 20% had attempted suicide in the previous 12 months. Toomey, Syvertsen and Shramko (2018) examined prevalence rates of suicidal behavior in American adolescents across six gender identity groups including female, male, male-to-female transgender, female-to-male transgender, other transgender (not exclusively male or female) and questioning. Overall 14% reported a previous suicide attempt. The most at-risk group was female-to-male transgender of whom 50.8% had attempted suicide, compared with 17.6% of cisgender (majority) female and 9.8% of cisgender male adolescents.

Clark et al., (2014) reported high levels of victimization for gender minority students, which is likely to contribute to the poor mental health of these teenagers. Consistent with this, a systematic review of the effects of cyber bullying on lesbian, gay, bi-sexual, transgender and questioning (LGBTQ) youth reported a wide range of negative associates of cyber bullying including suicidal ideation and attempts, depression, lower self-esteem, physical aggression and lower academic performance (Abreu & Kenny, 2018.)

Given the high risk of victimization and mental health problems for transgender youth and other gender minority groups, it is important to identify risk and protective factors. In a recent systematic review, Hall (2018) examined risk and protective factors for depression in lesbian, gay, bisexual and other queer youth. Hall reported that increased risk of depression was associated with school bullying victimization as well as stress from oppressing or hiding identity, having a socially stigmatized identity, maladaptive coping, parental rejection, abuse and other traumatic events, negative interpersonal interactions, negative religious experiences and violent victimization in community settings. Hall identified social support from friends, and family support as being negatively associated with depression.

A cross-sectional study by Simons, Schrage, Clark, Belzer and Olson (2013) found that parental support was significantly associated with higher life satisfaction, lower perceived burden of being transgender, and fewer depressive symptoms. A large cross-sectional study of transgender and other minority gender adolescents found that over half had self-harmed in the past year and that higher levels of victimization by peers and lower levels of family connectedness distinguished those who had attempted suicide (Taliaferro, McMorris, Rider & Eisenberg, 2018). This is consistent with other research that shows that positive peer and family relationships protect against victimization and internalizing problems (Bowes et al., 2010;

Healy & Sanders, 2018). This reinforces the importance of family support for gender minority adolescents, in general, and particularly when they are dealing with bullying victimization and faced with lack of support from peers.

Unfortunately, however, the process of gaining peer and family support for gender minority youth can, in itself, be fraught with risk. As found by Hall (2018), oppressing or hiding identity was associated with increased risk of depression for adolescents. This is consistent with findings of Russell, Toomey, Ryan and Diaz (2014) who, in a retrospective study of young LGBT adults, found that, after controlling for school victimization and later adjustment, being “out” at high school was associated with positive psychosocial adjustment in young adulthood. Despite the potential support benefits of disclosing their gender or sexual identity, Russell et al. explained that disclosure to peers may also risk rejection and potentially trigger victimization, which is associated with poorer adjustment. This dilemma may contribute to the very high rates of depression for these minority groups.

The risk of disclosing at school suggests that family support may be especially important in influencing outcomes for these at-risk students. McConnell, Birkett and Mustanski (2016) investigated mental health trajectories of LGBT youth using a longitudinal study based on eight waves of data collection over five years. The researchers differentiated between three levels of social support: uniformly low support, uniformly high support, and non-family support (i.e., high peer and significant other but low family support). After controlling for age, victimization, and social support, the researchers found that youth in both the “low support” and “non-family support” clusters reported greater distress across all time points relative to youth in the high support cluster. Those who lacked family support, but had other forms of support, reported a decrease in psychological distress and an increase in family support across adolescence. However, youth who were low in all forms of support continued to exhibit high distress across the whole monitoring period. This study highlights the crucial role that parental and family support plays for these highly vulnerable teenagers.

CONCLUSION AND RECOMMENDATIONS

The aim of this chapter was to examine how gender influences the relationship between parenting and children’s involvement in bullying. This was contextualized in an understanding of gender differences in involvement in bullying in general, and a theoretical overview, and review of evidence, for how parenting affects children’s involvement in bullying.

Being bullied at school greatly increases a child’s risk of serious ongoing mental health problems including depression, psychosis and self-harm. Children who perpetrate bullying are also at risk of later delinquency. There is a great deal of evidence that parenting influences children’s behavior and relationships with peers, including their perpetration of bullying and victimization. Parenting also protects children from the risk of internalizing problems, both directly, and through supporting children’s friendships.

A body of research has examined gender differences in the relationship between parenting and children’s involvement in bullying. Most of this research is cross-sectional only and does not take into account the possibility of bi-causal relationships between parenting and children’s behavior. Many studies are based on student reports only, including of parenting style. A further limitation is that few studies include fathers, which may be important in determining whether

child gender differentially affects the relationship between parenting and involvement in bullying.

Despite these limitations, there are some consistent findings. Firstly warm, supportive parenting helps children learn to develop close supportive friendships with others and is likely to prevent both bullying and victimization. Lack of a warm relationship with mothers may be more detrimental for girls than boys, and may increase risk of peer victimization. To prevent both bullying and victimization, it is helpful for parents to encourage children to develop independence within reasonable boundaries of supervision. Too much restriction may prevent children learning to self-manage, which may leave them vulnerable to victimization. Too little parental monitoring may allow conduct problems and bullying to develop without correction. Coercive parenting and lack of supervision may be particular risk factors for boys' involvement in bullying. Finally, abusive parenting is damaging to all children, irrespective of gender, and may interfere with children's development of empathy and trust in relationships, which may compromise the quality of relationships they are able to develop with peers, and leave them vulnerable to involvement in bullying, as both victims and perpetrators.

As previously mentioned, meta-analyses of school anti-bullying interventions show that, although they provide some benefit (at least in primary school), they do not do enough to address the serious risks posed by bullying. A recent study by Kaufman, Kretschmer, Huitsing and Veenstra (2018) investigated why some children continue to be bullied despite participation in school anti-bullying interventions. Using data from middle and high school students who participated in studies of the KiVa anti-bullying intervention, Kaufman et al. found that children who experienced particularly high levels of peer rejection, internalizing problems, and lower quality parent-child relationships showed less improvement, and concluded that these characteristics appeared to contribute to persistent victimization.

Kretschmer et al. (2018) called for tailored interventions to reduce victimization for more children. This could include interventions involving parents. Healy and Sanders (2014) reported the RCT of a targeted family program that combined facilitative parenting and social skills training for children bullied by peers; children in the intervention condition had greater reductions in victimization by peers than children in the control condition. Another way of addressing bullying through parenting is ensuring that school anti-bullying programs include education for parents about how to support their child in their relationships with peers. The meta-analysis by Ttofi and Farrington (2011) found that having parent meetings was one of the strategies that differentiated effective from ineffective school interventions. Incorporating parental education into school interventions may help parents to prevent children's involvement in bullying.

For many decades research on gender and victimization has overlooked students who are highly at risk: transgender and other gender minority groups who do not fit into the assumed male/female dichotomy. Recent research suggests these students, although small in number, are at greatly increased risk for depression, self-harm and suicide, with victimization by peers being a contributing factor. Supportive relationships with parents are particularly important for these students, especially if they are not receiving support from peers. Further research on interventions to support children who are bullied could investigate how best to encourage parents to support children who may be gender diverse.

Chapter 39

PREVENTION AND PSYCHO-PEDAGOGICAL CORRECTION OF BULLYING IN SCHOOL: RUSSIAN PERSPECTIVE

Roza A. Valeeva* and Laysan A. Ribakova

Institute of Psychology and Education, Kazan Federal University, Kazan, Russia

ABSTRACT

The problem of violence and aggression is significant and has been studied for many years. Teachers and school psychologists are increasingly turning their attention to the problem of violence among students. In Russia, the violence at school was called baiting. Foreign researchers call this phenomenon ‘bullying,’ and this term is now in common use in the Russian pedagogy.

In spite of the new term, bullying describes the old phenomenon of children’s cruelty. The problem of bullying is particularly important in early adolescence because, at this age, having learned certain behaviors, such as the behavior of a “victim,” the individual may adopt it in the future. It should be noted that bullying has a negative affect, not only on the “victims,” but also the “persecutors.” If the demonstration of aggression satisfies on the child, it can be fixed as the dominant behavioural style in later life. Thus, violence in school (bullying) requires particular attention for the early teens.

For many years in Russian psychological and pedagogical studies the problem of bullying was not researched. There was no scientific term for the problem, since the concept of “baiting “ was not seen as equivalent to “bullying.” So, although bullying is extremely important, it is difficult to find information about it in Russian studies.

This study examines the theoretical justification and experimental verification various methods to ensure effective prevention and psycho-pedagogical correction of bullying in school. Fifty three teenage students from Kazan took part in the experiment.

It used a mix of diagnostic techniques for the detection of violence and bullying in the school environment: the *Questionnaire for diagnosis of violence and bullying at school* by Su-Jeong Kim (modified by Petrosyan), The *Buss-Durkee Hostility Inventory* (BDI), and the *Questionnaire for the diagnosis of the capacity for empathy* by Mehrabien & Epstein.

* Corresponding Author’s Email: valeykin@yandex.ru.

A statistical analysis of empirical research was carried out by standard techniques of mathematical statistics (Student's *t* test, and Pearson's correlation coefficient).

From the experimental work experiment the authors developed a program for the prevention and psycho-pedagogical correction of bullying among younger teenagers in school.

Keywords: bullying, prevention, correction, school, younger teenager

1. INTRODUCTION

1.1. Identifying the Problem

The problem of violence and aggression is significant and has been studied for many years.

Teachers and school psychologists are increasingly turning their attention to the problem of violence among students. In Russia, the violence at school was called baiting. Foreign researchers call this phenomenon 'bullying,' and this term is now in common use in the Russian pedagogy.

In spite of the new term, bullying describes the old phenomenon of children's cruelty. The problem of bullying is particularly important in early adolescence because, at this age, having learned certain behaviors, such as the behavior of a "victim," the individual may adopt it in the future. It should be noted that bullying has a negative affect, not only on the "victims," but also the "persecutors." If the demonstration of aggression satisfies the child, it can become fixed as the dominant behavioural style in later life. Thus, violence in school (bullying) requires particular attention for the early teens.

For many years in Russian psychological and pedagogical studies the problem of bullying was not researched. There was no scientific term for the problem, since the concept of "baiting" was not seen as equivalent to "bullying." So, although bullying is extremely important, it is difficult to find information about it in Russian studies.

In contrast in the West the problem of bullying has achieved considerable importance (Ribakova, Valeeva & Merker, 2016).

Some researches define bullying as serious acts of aggression, while others include any insults and threats. In either case it is clear that we are talking about a serious and widespread phenomenon.

The media often reports on cases of children bullying teachers and their classmates. But this is just the tip of the iceberg. The bulk of the problem is under the surface and remains unavailable to the masses. Though the problem is widely discussed, the practical actions to solve it are not reported. According to Pronin (2008), violent relationships between students are common. With each school there is usually one class where this is endemic. The relevance of this research comes from the fact that the current problem of bullying in the schools is more prevalent, and affects all parts of the school. School bullying among younger teenagers has its own characteristics. This is an age which is very important for children's inter-personal communication and strengthening their position in the group. Some students may use bullying to establish their position (Kostyunina & Valeeva, 2015; Ribakova, Valeeva & Merker, 2016).

Bullying among younger teenagers can take one of three forms of deviant behavior - conformal, victimization or aggression - and accordingly they assume the rôle of a witness,

victim or persecutor. Children who are victims of bullying from classmates, do not often speak about it. Thus the inner circle of the child's family and friends should be alert to any changes in the child's behavior, noting the key behavioral characteristics which are typical for victims of bullying.

1.2. Status of the Problem

An analysis of scientific literature shows that the prevention and investigation of the problem of psycho-pedagogical correction of bullying began in 1905, when the first works were published on the topic of school bullying. The pioneers in this area, who conducted the first systematic study of the bullying problem were the Scandinavian scientists D. Olweus (1978), E. Roland & E. Munthe (1989). In particular, Olweus was most influential in this area. Later research in the UK was carried out by Tattum & Lane (1988). More recently, in the 1990s, particular attention to the problem was paid in the United States.

There is a wide variety of definitions of bullying, but none is clearly formulated and universally accepted. Authors studying this phenomenon, use different definitions of bullying, based on their understanding.

For example, the therapist Berdyshev (2005: 3) gives the following definition of bullying: "a conscious, sustained violence, not having the character of self-defense and coming from one or more persons" while the sociologist Kon (2006:15) believes that bullying is "intimidation, physical or psychological terror that seeks to cause fear in another, and thus subjugate it." Arora (1994) calls bullying the actions that are observable and have a place in the communication between young people at school and are the cause of resentment and stress. Besag (1989) investigated the problem of bullying in schools, and concluded that bullying is a behavior which can be defined as repeated physical, psychological, verbal, or social attacks of those whose power is situational or formally above, on those who don't have the possibility to protect themselves, with the intent to cause suffering and to achieve personal satisfaction.

Based on the works of Lane (2001) and Roland (1989) the Russian scientist Ilyin (2014), defines bullying as a systematic long-term physical or mental violence, carried out by one person or group and directed against a person who is unable to defend himself in the actual situation with the conscious desire to hurt, frighten or to subject prolonged stress.

In order to explore the essence of bullying, it is necessary to consider the "bullying-structure" suggested by Roland (1989), that it is a social system that includes offenders (pursuers, aggressors, hooligans), and their victims and witnesses (observers).

1.2.1. "Offenders"

Olweus (1978) notes that "offenders" can be described as individuals with high potential of general aggression. They "attack" not only their victims, but also the family and teachers, and have more positive attitude toward aggression than the "witnesses" and "victims." They demonstrate lack of empathy for "victims" and have a relatively high need to dominate over others. The "offenders" also have a strong need for the management of children and getting satisfaction from their subordination.

Any child can become a victim, but it is usually someone who is somehow different from the others or weaker that is chosen. The most frequent victims of school violence are children who have weaknesses in physical development, specific appearance or behavior. Very often

withdrawn children (phlegmatic and introverts) or conversely, children with impulsive behavior become the victims of ridicule and aggression. Hyperactive children may act both as victims and offenders - and often at the same time. School phobia, poor social skills, the lack of group interaction experience (children educated at home), learning difficulties and low intelligence, or some disease often makes the children victims of bullying.

1.2.2. “Witnesses”

It is difficult to highlight characteristic features of a “witness” because, in bullying situations the majority of children act as “witnesses.” It has been shown that the self-esteem of these children is markedly reduced because of the feeling of their own helplessness,. Outside observers often talk about their sense of powerlessness and guilt. Askew (1989) argues that in a bullying situation not only the “victim” who suffers, but surrounding people suffer by not having the strength and opportunity to rebuff the abuser.

Numerous studies show that the manifestations of bullying in school are due primarily to the fact that school is a universal arena, a place for children to release their accumulated at home negative impulses. The children see and accept rôle relationships between “a leader and a rogue.” Another factor contributing to the growth of bullying in school is the inability of teachers to resolve this problem.

Researchers define differing forms in which bullying is expressed. Thus, Lane (2001) speaks of physical and mental violence, Berdyshev (2005) asserts the existence of behavioral, verbal and actual aggressive bullying, with the presence of physical violence, and Mertsalova (2000) emphasizes the existence of emotional, physical, verbal and mental abuse.

School bullying includes manifestations of the pursuer against a victim, but according to Malkina-Pykh (2005), these are aimed, at humiliation by physical, emotional or economic violence and aggression. Let us look at the content of each of these types of violence.

Physical violence is the use of physical force against a student, resulting in possible severe physical injuries of varying severity. Physical violence includes striking, cuffing, beating, slapping, and property damage. As a result of these actions books, clothing and other personal belongings of the victims may be damaged, stolen or hidden. In some cases, it may involve the use of the weapon (for example knives). According to Malkina-Pykh (2005), this behavior is more common among boys. Very often physical violence is accompanied by emotional violence. The use of physical force may persist for a long time, thus causing traumatic experiences for the victims.

Emotional abuse, causing the victim emotional stress, lowers their self-esteem and humiliates them. In this case, the main weapon is the voice. There are several types of emotional abuse:

- refusal of communication with the victim, isolation, or rejection. As a rule, the use of this method is initiated by a bully. The victim is deliberately ignored by a part of a class or a class - expelled or isolated. It is often accompanied by humiliating slogans on the board or in public places, whispered insults that can be heard by the victim, the spread of the notes that have offensive content. They encourage others to reject the child. “Don’t play with him,” “don’t invite him to birthday parties,” “do not let him sit at the same desk,”

- biased evaluation and endless notes, assigning nicknames, which are constantly referring to the child, thereby insulting and injuring them, ridicule, mockery, and humiliation in front of other children, and so on. This kind of bullying is often used against victims with high or low academic performance, obvious differences in physical appearance, accent or voice features. Name-calling can also take the form of hints about the student's alleged sexual orientation. The use of anonymous phone calls is a common form of verbal bullying, in which not only students, but even teachers may become victims;

Economic violence involves the use of the money to control another person. In this case money is demanded from the victim, followed by threats if they do not hand it over immediately. Breakfasts money or lunch coupons can also be extorted. It is possible to force the victim to steal property with the aim of making the blame fall on the victim.

Maltseva (2009) writes about a recent kind of school bullying – cyberbullying in which the victim is abused by e-mail or, increasingly by social media.

Thus, bullying can be considered as intentional, repeated and sustained psychological or physical violence, unlike self-defense or sanctions authorized by the state, which comes from an individual or a group having certain advantages (administrative, psychological, physical) with respect to a person, and which occurs mainly in organized groups with a specific personal goal.

The bullying process is largely hidden from others, but its latency does not make it less dangerous. Children who are subjected to harassment, may receive psychological trauma of varying severity, with possible negative consequences. It does not matter whether it is physical or psychological bullying. Preventing school violence is one of the most important tasks of the teaching staff, because the cruel treatment of a child inevitably leads to serious consequences.

1.3. Bullying in Younger Adolescence

The likelihood of bullying is particularly high in younger adolescents, and its consequences can be extremely negative.

The origins of bullying among younger adolescents include:

1. Individual factors (conformity, victimization and aggression of adolescents).
2. Group factors (unfavorable socio-psychological climate of the group, antisocial group activity, lack of a unified value-orientation, unformed self-determination of the individual within the group members).

The emergence of various types of deviant behavior in adolescents, manifested in bullying, creates the prerequisites for its appearance in the classroom. Bullying is connected with various types of deviant behavior such as conformal, victimized, and aggressive. Depending on the type of deviant behavior, the child may assume the rôle of a witness, a victim or a stalker when bullying takes place.

Positive attitudes, the effectiveness of learning activities and prosocial norms are closely interrelated and have a significant impact on the susceptibility to bullying among younger adolescents. By activating mechanisms that restraining active aggression of adolescents, norms can be established to show that bullying is unacceptable.

Effective student learning can reduce bullying. Episodes of bullying in younger adolescents often occur during lessons, but when the class focuses on learning activities, students are less distracted and less likely to disturb others, and so misconduct is reduced. This in itself should reduce bullying, since hooliganism, disorder and bullying are interrelated and probably reinforce each other. Furthermore, learning productivity is part of a normative system which not only prohibits, for example hooliganism and disorder, but provides clear guidelines for the normal and the desired behaviour.

Favorable relationships within the class can also reduce the risk of bullying. Bullying victims are often loners. If in the class as a whole, everyone treats each other well, then the potential victims will probably have friends, and this provides a defense against proactive aggression. The probability for potential pursuers and potential victims to have the same positive connections increases significantly, and this makes it possible to avoid bullying.

Favorable student relationships have another effect on proactive aggression. If the class is friendly, then tensions between its members are less. Tension occurs when there is a certain mismatch or imbalance of sympathy. If the class is unfriendly, individual students may have a power motive because it is pleasant to subjugate a person who you do not like, and this in turn, will lead to increased proactive aggression.

There are also gender differences in the manifestation of bullying in younger adolescence. The research of Olweus (1993), Lane (2001), Besag (1989), Berdyshev (2005), Kon (2006), and Maltseva (2009) identified that

- there are differences in the types of bullying in males and females;
- it is more difficult to cope with the problem of bullying for girls;
- female bullying is more personalized, psychologically oriented and more emotionally destructive;
- bullying among boys is primarily associated with the struggle for power;
- the peculiarities of bullying in males are associated with a young male normative culture.

As a rule, the victims of bullying do not report that they have been bullied but you can learn about this from the mood and behavior of the child. A teenager who has become a victim often feels depressed and defenseless against a pursuer. This leads to a fear of everything and everyone, a feeling of constant danger, insecurity and, a consequent loss of faith in one's own strength and self-esteem. The victim really remains defenseless against the actions of the offenders. Episodes of cruel bullying can lead a younger teenager to suicide and so those involved with the child need to pay utmost attention to even the most minor changes in behavior.

The following features are characteristic for adolescent victims of bullying:

- there are obvious symptoms of fear, including secrecy and solitude, disturbances of appetite and sleep, enuresis (bed-wetting), crying at night, nervous tics and stuttering;

- they often pretend to be sick, so as not to attend school;
- they are afraid to go to school and return home alone, parents are asked to take them to classes, and they are often late;
- a decline in the quality of study, and loss of interest even in hobbies;
- they often ask for money and sometimes even steal;
- they become silent, unwilling to talk;
- there are permanent bruises, abrasions and other injuries;
- suicidal intentions or even suicide (Tattum, & Lane, 1988).

Thus, in younger adolescence:

1. it is important for a teenager to his place in groups, and he can use bullying to achieve this goal;
2. younger adolescents can adopt three types of deviant behavior in a bullying situation - conformal, victimized, aggressive;
3. there are factors that can prevent bullying in the early teens. These include positive relationships, the effectiveness of learning activities and prosocial norms, which are closely related to each other;
4. there are gender differences in the manifestation of adolescents' bullying;
5. adolescent victims are often characterized by certain features and behavioral changes.

1.4. Prevention and the Psychological and Pedagogical Correction of Bullying

Analysis of the literature and practice reveals a contradiction between the increasing need for active work aimed at combating school violence and the insufficient development of the content, forms and methods of preventive and corrective work aimed at reducing bullying in school.

Professional use of prevention and psychological-pedagogical correction is key to overcoming school bullying. Prevention involves a set of measures aimed at understanding and reducing the level of bullying as a stereotype of behavior in educational activities that can adversely affect students' physical and mental health.

The prevention of bullying is based on the basic principles of a humane approach to a child, recognition of the family as the most important institution of prevention, coordinated action of all educational and preventive services in the micro-environment, maximum individualization and targeting of preventive effects in society, and the constructive use of preventive measures.

Psychological and pedagogical correction is the joint professional responsibility of the psychologist, teacher and parents, based on a system of psychological influences with the goal of correcting a child's mental development disorders. This is based on the knowledge of individual, age and sociocultural development norms. At the same time, remedial work is aimed at creating conditions for the full mental development of each child in their family and educational setting.

In setting correctional goals, the psychologist is guided by knowledge and understanding of the child's mental development as a dynamic process, ideas about the dynamics and structure

of age, psychological information about the socio-cultural situation of development of each child, and activity theory in the formation of age-related neoplasms.

In implementing a comprehensive preventive and correctional program to overcome bullying, it is necessary to take into account the following psychological and pedagogical principles:

- unified diagnosis and correction;
- systematic character of preventive, developmental and correctional tasks;
- accounting of individual and age-psychological features of the client;
- priority of causal type correction;
- active involvement in the program of the closest social environment;
- the complexity of the methods of psychological influence.

Dealing with the problem of harassment and rejection of some children by others can be achieved by working with the rejected children (both individually and in a group), or with the class as a whole.

Individual work with the rejected children.

After identifying the unpopular or rejected child, it is necessary:

1. To get to know this student more closely.
2. To diagnose the personal characteristics of the child.
3. To watch the child during breaks and in the class during lessons.
4. To talk with the child about the situation in the classroom, his or her interests, and discover the problems of interaction.

Individual work with a child victim contributes not only to a better understanding of the causes of what is happening but the conversations are important for the child himself. With such meetings, the student no longer feels useless and lonely at school. However, it is impossible to help a child in a situation of bullying solely by talking only. The child must learn to interact with others and this is possible only in group classes.

Group classes with the rejected children.

Working in groups of unpopular children can have a significant effect. As with any modality, group classes have their own characteristics. It is desirable that the group has an even number of children because it is necessary to give every child the opportunity to work with everyone - not only with pleasing, but also unpleasant partners. It is better to start each lesson with exercises aimed at immersion in an activity, then proceed to exercises on arbitrariness or outdoor games. Then one can conduct an exercise to discuss things together, playing and discussing scenes, and in the end, offer something pleasant and fun for everyone that allows self expression. Feedback is extremely important and each participant should have the opportunity to speak.

Working with a group or class.

It is not sufficient to work just with the victims to overcome the negative attitude of classmates towards unpopular children: it is necessary to work with the whole group. Such classes allows the rejected child expressing him/themselves. Classmates begin to look at them

in a new way, in an unusual situation and begin to treat them with more interest and concern. As a rule, children attend such classes quite willingly.

One of the main areas of psychological work with the unfriendly class exhibiting cases of bullying should be activities aimed at developing tolerance. It is lack of tolerance for the characteristics of another and on their dissimilarity, that persecutions are based. Activities are also needed to develop self-confidence and to form an attitude of non-violence.

Psychological and pedagogical correctional work should not be limited to eliminating the aggression of some children towards others. It is necessary to eliminate the causes leading to its manifestation and to expand the tools that are actively used in the child's behavior.

Psychological and pedagogical practice and literature identify directions of work for prevention and correction of bullying which include:

- the formation in children of personal qualities such as trust in people and empathy. An effective way of implementing this is to induce incompatible reactions, such as laughter and humor, as well as a focus on the state of other people;
- developing the ability in children to control themselves and training them in self-regulation techniques and the practice of communication skills in possible conflict situations;
- teaching aggressive children how to express anger in a socially acceptable form.

Preventive and remedial programs against bullying can include conversations, exercises, rôle-playing, writing, watching movies, reading literature, watching and staging rôle-plays. These activities can be used both separately and in combination:

Exercises involve multiple actions and repetitions in order to develop habits. They are necessary to form a positive attitude in younger adolescents, as well as certain moral skills and habits.

Rôle-plays on the topic of bullying have a strong effect because the actors and the audience are in the same room in close proximity to each other. This has a strong impact on students. In some countries schools cooperate successfully with acting troupes. The class or the whole school can stage a play about bullying independently. Through this means, schoolchildren-actors can learn a lot about themselves, and later become good rôle models for other children. The scenario of the performance can be written independently. If this is done in conjunction with the class, the psychologist together with the students must understand the material, and find appropriate examples, thereby increasing the level of awareness. The psychologist may choose specific students for certain rôles.

The rôle-playing method is a game-based method of active learning, characterized by the following main features:

1. the presence of tasks and problems and the distribution of rôles between the participants;
2. the interaction of participants, usually through discussion. Each of the participants may, in the course of the discussion, agree or disagree with the opinion of the others;

3. corrective input by the teacher during the class. Thus, s/he can interrupt the discussion and give some new information that needs to be taken into account when solving the task, turning the discussion to another direction, etc;
4. evaluation of the results of the discussion and summarizing by the teacher.

A group of adolescents who play a rôle is likened to a group of children playing a school, hospital, shop, etc. A rôle-playing group unconsciously creates their own reality and, with this, the participants operate with their knowledge of the real world, developing their abilities to interact with other people without the risks inherent in the real world. There are no spectators in this situation. The improvised activities are fun and do not threaten the child. rôleRôle-play strengthens rather than destroys self-confidence. rôleRôle-play offers a number of advantages:

1. It can exceed the possibilities of any pair and group activity in developing teenagers' ability to speak in any situation on any topic.
2. It puts participants in situations in which they need to use and develop language that can lubricate the social relationships that teachers so often neglect.
3. It provides shy, insecure adolescents raised in an orphanage with a "mask" they can hide behind. Teenagers have great difficulties when the main focus is on their personality and on their direct experience. In a rôle-playing game, these participants are exempt; since their identity is not affected, they need not be revealed.
4. It gives children pleasure. As soon as the participants begin to understand what is required of them, they gladly give vent to their imagination.

If games are processed, memorized and played for the audience then they are no longer rôle-play, but become dramatic performances. The essence of rôle-play Rôle is the process, not the finished product and this must be understood from the very beginning. In contrast to a dramatic performance, there is no public – only the participants.

The main goal of such games in combating bullying is to make students feel for themselves what bullying is. To do this, students should be able to get used to the rôle. The peculiarity of rôle-play is that offenders may experience greater aggression, compared with their experience of participating in the formulation and adhering to a previously written script. They also have the opportunity to understand better the strategies spontaneously selected during the game. At the same time, in the course of the rôle-play, the victim will also be more affected by the pressure of the offenders than in a scenario setting. The student who plays the victim will be able to learn a great deal from this experience. The psychologist can repeat the game by changing the rôle of students. At the end, a discussion is held with all the students, not only those who participated in the game, but also those who observing it.

When watching feature films or special films reflecting bullying, most students are filled with feelings of the victim when they see what is happening on the screen. This gives the psychologist the opportunity to give students a voice and to give the necessary explanations. It is important that the psychologist choses the film based on his professional assessment and watches it with the students.

A popular approach in the prevention and psychological-pedagogical correction of bullying is to use literary works that deal with the problems. Students experience empathy and

understanding through the process of reading. The appropriate literature can be selected for each age group, so that children are able to identify themselves with heroes who are suffering. A psychologist can read a book aloud, talking about bullying, and the fears of the victim of persecution.

In books devoted to this problem, there are often characters who oppose the persecution, despite the danger that threatens them. Such characters can inspire indecisive schoolchildren who are not yet capable of discouraging bullying and violence. This way of using literature is a part of cognitive training. The text adjusts, helps to form moral values and landmarks, and awakens empathy. These texts often offer patterns of action and this contributes to social training.

Students can be given a task (at home or in the classroom) to write a short essay on bullying. The assignment can specify the issues to be reflected. From a psychological viewpoint, it is extremely important that the process of writing an essay enables pupils to more deeply understand the problem of bullying. The essays may reveal important information for the psychologist, such as the author's inclination, about which, which the student cannot speak directly for some reason. When reading an essay, a psychologist can leave comments on the margins.

One can choose several essays with important issues and, with the consent of the authors, read them to the class (perhaps the student himself can do this). The effectiveness will be greater if the essays of several students are read aloud. The psychologist gets the opportunity to express his position through comments after the readings.

The impact of talks about bullying will be maximised if the discussion of the topic becomes a natural component of everyday school life. At the same time, discussions of the topic should be regular, to ensure that the issue is not left unattended for long. Frequent and short conversations are more effective than long and infrequent ones. One might talk about bullying with the class once a week during the discussion of various topical issues. Where there is a need, it is necessary to dwell on this issue in more detail. Usually such a conversation is conducted by the class teacher. You can start with the clearly worded question such as: "Have any of you been bullied lately?," "Have any of you mocked others last week?" then look at the students and wait. If necessary, the teacher can take the initiative and say that s/he knows the facts of the persecution, or commend the students who helped the classmate who was being bullied.

A short weekly discussion on bullying is very effective. In this case, students always have the feeling that the school and the teacher will not tolerate harassment, and good deeds will not go unnoticed and will be appreciated. But it is important that such conversations do not become just a formal ritual, which is carried out for the sake of a tick. If so, they will lead to the opposite result.

Training is also effective in the prevention and psychological-pedagogical correction of bullying. Training is an active learning method aimed at developing knowledge, skills and social settings. Training can be used where the desired result is not only obtaining new information, but also applying the knowledge gained in practice.

Training can be considered from the point of view of different paradigms:

- as a means of forming the necessary patterns of behavior with the help of positive reinforcement, and using negative reinforcement to erase unwanted patterns;

- as a means of the formation and development of skills;
- as a form of active learning, the purpose of which is the transfer of knowledge, and the development of certain skills;
- as a method of creating the conditions for participants' self-disclosure and their search for ways of solving their own psychological problems.

There is no unified and generally accepted classification of training. In our study, we focused on socio-psychological training.

In a broad sense, socio-psychological training is any active socio-psychological teaching based on the mechanisms of group interaction (as opposed to, for example, training on the development of cognitive processes - attention, memory, thinking, etc.). Thus, Petrovskaya (2009) and Ann (2003) describe this as psychological influence, based on active methods of group work.

Compared with the individual format, group work with adolescents has several advantages:

1. Group experience counteracts alienation, and helps in solving interpersonal problems.
2. The group reflects society in miniature, revealing hidden factors such as peer pressure. The group simulates a system of relationships and interrelations characteristic of real life. This makes it possible to see and analyze the patterns of communication and the behavior of other people and themselves, which are not obvious in everyday situations.
3. It affords the possibility of obtaining feedback from children with similar problems. In real life, not everyone has a chance to get sincere, non-judgmental feedback that allows them to see themselves in the eyes of other people.
4. In a group, adolescents can identify with others, and "play" the rôle of another person in order to better understand himself and to get acquainted with new effective behaviors used by others. The resulting emotional connection and empathy contribute to personal growth and the development of self-awareness.
5. The group facilitates the processes of self-discovery, self-inquiry and self-knowledge; these processes cannot be complete without the participation of other people. Opening yourself to others and opening yourself to yourself allows self-understanding and increasing self-confidence.

In order to overcome school bullying, it is necessary to work with parents and discuss its causes with them. When talking to the parents of the perpetrators, it is important to be cautious in making assessments. Children from dysfunctional families are often guilty of bullying. In communicating with the parents of the victims, there is a danger of taking the position of protecting the "uniform," that is, attempting to protect the school's reputation, rather than the child who rôlebecame the victim. When talking about what can and should be done to change the situation for the better, we must try to solve this problem together.

Thus, in the process of the preventive and correctional program of bullying, we should employ a model of behavior change, which allows us to:

- develop the child's awareness and acceptance of himself, his emotional needs and his needs;
- to accept the needs and emotions of other people, combined with the development of skills to meet the needs and express negative emotions in socially acceptable forms.

Preventive and remedial work can be carried out both separately with victims and offenders, and with the whole class together. In our opinion, the second option is more effective, since it is joint work that is the easiest way for students to adopt each other. The most effective forms and methods are training, working with literature, games (rôle-playing, etc.) and exercises. These methods were used when creating our correctional program.

2. METHODS

2.1. The Research Task

The purpose of the study was the theoretical justification and experimental verification of content, complex forms and methods to ensure effective prevention and psycho-pedagogical correction of bullying in school.

2.2. Theoretical and Empirical Methods

The study employed both theoretical (the study and analysis of pedagogical and psychological literature, comparisons and generalizations) and empirical (note-taking, and a control experiment) methods

The results were processed with Student's t-criterion.

In order to identify violence and bullying in the school environment the study employed the questionnaire for diagnosis of violence and bullying at school» developed by Su-Jeong Kim (Petrosyan's modification), together with the Buss-Durkee Hostility Inventory (BDI) (1957), and the Questionnaire for the diagnosis of the capacity for empathy by Mehrabien & Epstein (1972).

The questionnaire for diagnosis of violence and bullying at school by Su-Jeong Kim (with Petrosyan's modification) (Kim, 2004; Petrosyan, 2011) consists of two parts. (1) "Violence in Schools" (12 points), and (2) "The situation of bullying in school" (11 points). This modification provides an assessment of most of the indicators of bullying discussed in the theoretical review. Its purpose is to study the frequency of violence (psychological and physical), experienced and exhibited by a child, as well as recognising himself as a persecutor or a victim of psychological and/or physical violence. It addresses issues that evaluate experience in bullying and are taken from the questionnaire by Kwak & Lee (1988). Some questions were added by the author of the modified version. Petrosyan extracted questions about the frequency of bullying by different methods (7 points) from the questionnaire of Olweus. The methods passed the procedure for checking the validity and reliability of the questionnaire.

Kim's Questionnaire for diagnosis of violence and bullying at school as modified, identifies the following levels of bullying among students:

100-71 points – a high level of bullying. Children point out the presence of violence in school and a variety of types of bullying in relation to the students. Children experience negative emotions, fear, hatred, anger, horror, depression, apathy. Children note the presence of physical and mental violence.

70-40 points – the average level is characterized by the presence of violence in school; children experience negative emotions and the desire to respond in the same way; physical violence is dominant.

39-0 points – the lowest level is characterized by stable emotional atmosphere, the lack of physical and mental violence, and the absence of negative emotions.

The Buss-Durkee Hostility Inventory (1957) indicates the following reactions: physical aggression (the use of physical force against another person); indirect aggression aimed to another person; irritation (a willingness to manifest negative feelings at the slightest excuse, temper, rudeness); negativism (behaviors ranging from passive to active struggle against the established customs and laws); resentment (envy and hatred of the real and imaginary deeds); suspicion (from mistrust and caution in relation to the others to the belief that other people are planning to bring harm); verbal aggression (verbal expression of negative feelings); guilt expressing the person's conviction that he or she is "bad," as well as pricks of conscience. The technique allows also the researcher to allocate the index of hostility (resentment and suspicion) and the index of aggression (physical aggression, anger, verbal aggression).

Mehrabien & Epstein's "Questionnaire for the diagnosis of the capacity for empathy" (1972) consists of 33 proposals. During the study of the younger teens' capacity for empathy, four groups were distinguished: a high level of empathic tendencies, the average level of empathic tendencies, low empathic tendencies, and a very low level of empathic tendencies.

2.3. The Trial Infrastructure and Stages of the Research

An empirical study was conducted within the Gymnasium № 40 in Kazan (Republic of Russia) and involved 53 junior teenagers. The study was conducted in three stages: baselining, formative testing and control.

The aim of the initial experiment was to determine the baseline empathic tendencies, indicators of aggressiveness of adolescents, the level of bullying, and the overall presence of bullying in a group. Based on these results the program was developed containing a variety of forms and methods of prevention and psycho-pedagogical correction of bullying in school.

The purpose of the formative experiment was to test the program "Hand in Hand," aimed at the prevention and psycho-pedagogical correction of bullying in school. In the control phase of our experiment, we evaluated the effectiveness of the forms and methods of prevention and psycho-pedagogical correction of bullying by younger teenagers. At this stage, we identified the level of all the studied parameters and studied their dynamics.

Comparing the results that were obtained in the baseline and control stages of the experiment, we established whether the correct forms and methods of psycho-pedagogical correction had been applied and how they had reduced the situation of bullying in school. The experimental study was carried out in natural setting of the educational process of the school.

3. RESULTS

3.1. Experimental Procedure and Its Description

Initially, respondents were asked to answer Kim's Questionnaire for diagnosis of violence and bullying at school. With this technique, we identified particular manifestations of bullying in school, how respondents react in the situation of bullying, their attitudes, as well as how often they were exposed to bullying.

Next, we used the Buss-Durkee Hostility Inventory (BDI) to identify different types of aggression, characteristic of teenagers.

The responses were measured on eight scales as follows:

1. Physical aggression: "yes" = 1, "no" = 0: (items 1, 25, 31, 41, 48, 55, 62, 68); "no" = 1, "yes" = 0: (items 9, 7).
2. Indirect aggression: "yes" = 1, "no" = 0: (items 2, 10, 18, 34, 42, 56, 63); "no" = 1 "yes" = 0: (items 26, 49).
3. Irritation: "yes" = 1, "no" = 0: (items 3, 19, 27, 43, 50, 57, 64, 72); "no" = 1, "yes" = 0: (items 11, 35, 69).
4. Negativism: "yes" = 1, "no" = 0: (items 4, 12, 20, 28); "no" = 1, "yes" = 0: (item 36).
5. Resentment: "yes" = 1, "no" = 0: (items 5, 13, 21, 29, 37, 44, 51, 58).
6. Suspiciousness: "yes" = 1, "no" = 0: (items 6, 14, 22, 30, 38, 45, 52, 59); "yes" = 0, "no" = 1: (items 33, 66, 74, 75).
7. Verbal aggression: "yes" = 1, "no" = 0: (items 7, 15, 23, 31, 46, 53, 60, 71, 73); "yes" = 0, "no" = 1: (items 33, 66, 74, 75).
8. Feeling guilty: "yes" = 1, "no" = 0: (items 5, 8, 16, 24, 32, 40, 47, 54, 61, 67).

The hostility index includes items 5 and 6 of the scale and the aggressiveness index (straight or motivational) includes items 1, 3, 7..

The norm value of the aggression index is equal to $18 - 21 \pm 4$, and hostility - $6.5 - 7 \pm 3$. It demonstrates the possibility of reaching a certain value that shows the degree to which aggressiveness is manifest.

The Questionnaire for the diagnosis of the capacity for empathy" by Mehrabien & Epstein was used to determine the teenagers' level of empathy

Since we needed to define a common indicator of the presence of bullying in a group test, we employed arithmetic. When dividing the sample into three groups as a central subgroups we divided the subjects for which the indicator value x_i is within $x_{cp} \pm \sigma x$.

The availability of bullying in adolescents was defined as:

- low level 1-5 score
- average: 6-11 points,
- highest level: 12-15 points.

3.2. Experimental Results

During testing, a high level of empathic tendencies in the baseline stage of the study (from 33 to 26 points for boys, from 33 to 30 points for girls) was identified in 8 teenagers, accounting for 15.1% of the total number. An average level of empathic tendencies (from 25 to 17 points for boys, from 29 to 23 points for girls) was detected in 15 children, accounting for 28.3% of the total number. A low level of empathic tendencies (from 16 to 8 points for boys; 22 to 17 points for girls) was detected in 25 teenagers, accounting for 47.2% of the total number of participants. A very low level of empathic tendencies (7 to 0 points – for boys; 16 to 0 points – for girls) was detected in 5 people, or 9.4% of the total number of children (see Table 2).

Overall, taking into account the low and very low level of empathic tendencies in the studied group of teens, the group was dominated by low level of empathy. For example,

- The boys say that people exaggerate their ability to feel and experience;
- if a friend or girlfriend begin to discuss their problems, they try to turn the conversation to another topic;
- it is frustrating when people watching a movie sigh and cry;
- someone's laughter does not infect them;
- the opinion of other people, as a rule, does not matter when they make a decision.

We concluded that there was a need for special work to increase the young adolescents' level of empathy.

The next stage of our study was to investigate the aggressive reactions of adolescents in the baseline phase of the experiment. The dominant aggressive reaction in the group of teenagers was

- suspicion (12.8), ranging from mistrust and caution against people, to the belief that other people are harmful;
- verbal aggression (10.2), as the expression of negative feelings through the form (a cry, squeal), and through the verbal content of the responses (curses, threats);
- offense (5.6), jealousy and hatred of others for real and imaginary action;
- guilt (5.6) expresses the possible conviction of the child that they are a bad person acting badly, as well as feelings of remorse.

The dominant types of aggressive reaction are shown in Table 1.

We found the aggressiveness index in the group was 47.2%, while the index of hostility was 52.8%. Both of these are high values.

The next stage of the study was to determine the baseline level of bullying in the group. We found a high level of bullying in 26 adolescents – 49.1% of the group. Children identified the presence of violence in schools, and a variety of types of bullying in interrelations and negative emotions. Children experienced fear, hatred, anger, horror, depression, and apathy, and reported physical and mental violence.

An average level of bullying was found in 32.1% of the group (17 adolescents). This average level is characterized by the presence of violence in school, with children experiencing negative emotions and the desire to respond in the same way. Physical violence was dominant.

Before the experiment 18.8% of the group (10 adolescents) exhibited low level bullying. This was characterized by the stability of the emotional atmosphere, the lack of physical and mental violence, and the absence of negative emotions.

45.3% of the children believed that the problem of school violence existed. Among the most common forms of violence they identified rudeness (60.4%), mockery (52.8%) and humiliation (49.1%). Among the less common – deliberate destruction of another's property (9.4%), isolation (6.5%), and pushing down the stairs (4.3%). Furthermore, 62.3% of children have a desire to respond in kind. As for the children's sense of security in school, 67.9% answered that it depended of circumstances, and 32.1% felt totally secure. 49.1% of students experienced physical violence once or twice, 28.3% once a month. As for psychological violence, 71.7% of respondents experienced it once or twice, 32.1% once a month, and 17% once a week. 30.2% of children said that during the current half-year they were subjected to harassment once a week, 60.4% were subjected several times over the same period. However, 17% did not know why they were bullied by other students, 9.4% believed that it is due to the fact that others ignore them and the teacher liked them more, 18.8% thought it was because they often quarrelled with others, and 3.8% saw the reason being their financial position, because of their appearance and because they considered themselves better than the other students. 20.8% of bullied pupils pretended that nothing happened, 28.3% avoided places where it occurred, 15.1% did not talk to anyone, while 8.6% tried to explain that one cannot act this way and 3.8% missed school.

Table 4. Dominant aggressive reactions at baseline

Characteristic	
I know what people are saying about me behind my back	52.8%
I stay caution with people who treat me a little more friendly than I expect	60.4%
I think people do not like me	62.3%
I believe that many people envy me	49.1%
I think I am laughed at	45.3%
My principle is 'never trust strangers'	37.7%
If I do not approve of my friends' behaviour then I let them feel it	41.5%
I often do not agree with people	34%
I cannot resist a dispute if people do not agree with me	49.1%
I require people to respect me	67.9%
If someone annoys me I am ready to say what I think	77.4%
When someone cries I start screaming response	73.6%
I swear only in anger	32.1%
I often threaten people, although I am not going to carry out the threat	45.3%
I often raise my voice in a dispute	71.7%
I do not always get what I am entitled to	86.8%
I am almost always able to take advantage of favourable circumstances	88.7%
I am a little distressed by my fate	39.6%
I meet someone I do not like almost every week	83.0%

Table 5. (Continued)

Characteristic	
I am sometimes consumed with envy although I do not show it	30.2%
If everyone knew what I felt they would think that I am not easy to get on with	45.3%
I sometimes feel that life treats me unfairly	71.7%
I have experience pain and remorse when I have deceived someone	49.1%
I sometimes have thoughts (about aggression) of which I am ashamed	37.7%
I am upset that I do so little for my parents	32.1%
I do many things that I later regret	28.3%
I am distressed by failure	43.4%
I feel moral qualms when I do wrong	45.3%

Among the methods used by the students to solve the problem of harassment, (harassment opposition) were: talking about it with parents (28.3%), talking with the teachers (24.5%), and patience (18.8%). 62.3% of students witnessed bullying in the classroom, 43.3% of them tried to help the victim, but 25.9% did not do anything, although they had a desire to help, and 30.8% did not do anything because they felt it was not their business.
